Lettsomian Lectures
ON THE
SURGERY OF THE ARTERIES.

(ILLUSTRATED BY TWENTY-SEVEN OPERATIONS OF
LIGATURE BY THE AUTHOR, AND OTHER
CASES OF DISEASE AND INJURY.)

Delivered before the Medical Society of London, Jan. 1875,

By C. F. MAUNDER, F.R.C.S.,
SURGEON TO THE LONDON HOSPITAL.

LECTURE III.—Part I.

ON LIGATURE OF A MAIN ARTERY TO ARREST ACUTE TRAUMATIC INFLAMMATION.

Mr. President and Gentlemen,—The special subject of my discourse this evening—ligature of a main artery to arrest acute traumatic inflammation—was, when suggested to the profession by me, a novelty in Europe; but inasmuch as it was not so (as I afterwards learned to my chagrin) in America, I must, for both reasons, be allowed to give you a brief history of the matter, and to relate the illustrative cases somewhat in detail. A little time previous to this operation I had heard of *compression* of arteries being employed as a means to arrest inflammatory action. This information led up to the idea that *ligature* of the main artery would be a more effectual method. It will doubtless be accepted that cases of acute inflammation (of joints, for example) require speedy and active interference in order to bring about resolution—an admission in favour of the ligature. On the other hand, supposing compression to be resorted to, and, for some reason or other, to be relinquished too soon, blood would then not only pass to the inflamed spot through the enlarged smaller vessels, but also through the main channel, and thus an additional and injurious supply would be added.

On May 13th, 1866, I recommended the ligature of the femoral artery in a case of wound of the knee-joint followed by traumatic fever and acute inflammation below, about, within, and above the knee. The man who had sustained the accident was under the care of my then much-esteemed colleague, Mr. L. S. Little; and that gentleman tied the superficial femoral artery, with immediate and striking relief to symptoms. The patient, who was in imminent danger of losing, possibly, both limb and life, was from that moment in comparative safety, and made a good recovery.

Lacerated wound of the knee-joint; acute inflammation; ligature of superficial femoral artery; immediate relief; recovery.—Joseph C—— was admitted into the London Hospital, under the care of Mr. L. S. Little, on May 3rd, 1867, having sustained a lacerated wound, opening the knee-joint. When seen by Mr. Disney Thorpe, the house-surgeon, an hour after the accident, synovia was escaping. The wound was closed with three silver sutures, a back splint was applied, and the joint surrounded with bags of ice. He passed a good night without pain. The next day there was some effusion into the joint; but there was no heat nor constitutional disturbance.

May 5th.—Effusion less; patient very well. Ice to be continued, as he complains of pain if fresh ice is not frequently applied.

6th.—So well that he was placed upon full diet.

11th.—There is some redness along the inner side of the knee, and some pain.

12th.—Knee-joint much increased in size, red, and tense with fluid. Great and incessant pain, which is much aggravated if the joint be touched.

13th.—Joint still more swollen. It feels hot notwithstanding the continued application of three large bags of ice. The redness has extended some distance up the thigh, particularly on the inner side, where the tissues are brawny, also down the leg. The patient is suffering much from pain and sleeplessness, with a pulse of 120, anxious countenance, and general constitutional disturbance. At 10 A.M. he had a rigor. I now saw the patient in consultation with Mr. Little, and proposed the ligature of the superficial femoral artery as a means of arresting the inflammation. Mr. Little, courteously acting on my suggestion, boldly and dexterously tied the artery at once (4 P.M.) at the apex of Scarpa's triangle, the patient being under the influence of chloroform. The redness paled somewhat at once; and the patient, on recovering from chloroform, remarked, with surprise and delight, "my pain is gone." Half an hour after the operation the pulse was 100, having previously been 120.—10 P.M.: No pain since operation. Thinks he'll sleep. Pulse 96; less redness; toes cold, but sensible to touch.

14th.—4 P.M.: Toes warm; knee cooler and less red, but with a sense of numbness about it; pulse 90, feeble. To have six ounces of wine.

15th.—3.30 P.M.: Says he is "first-rate"; better appetite; heat about the heel prevented sleep (pressure from splint); knee and thigh smaller and paler; the ends of the accident wound began to discharge very thick pus about two hours ago; pulse 100, firmer; tongue cleaner.

16th.—4.30 P.M.: The patient had some starting pains during the night, so that he slept badly. As the discharge from the knee was now considerable, the quantity of wine was increased to ten ounces. Pulse 98.

17th.—During the night he had a profuse sudden bleeding from the nose.

June 1st.—Ligature removed to-day. Has gone on uninterruptedly well, with the exception that the wounds have been very slow in healing, and showed little power, particularly that on the thigh, which discharged very freely.

June 26th.—Sat up to-day.

P.S.—The patient gradually regained the use of his limb, and acquired free motion to the extent of 20°. Three months later the man was quite well, but the range of motion appeared to be limited by thickening outside the joint. He refused further interference, as he can do his work satisfactorily. He is here to-night.

I need scarcely say that when this idea of mine had been put in practice (1866) with pre-eminent success, it created considerable discussion in the profession, and many surgeons came to see the case. Since that time certain articles on inflammation published in this country have advocated this as one of the methods of treatment. Mr. Bryant says* "To arrest acute inflammation in a limb, the deligation of the main artery of the limb, or the arrest of the circulation through it by pressure upon the artery, has been adopted. Dr. Campbell, of New Orleans, speaks highly of the practice, and even affirms that no portion of an extremity should be amputated for destructive inflammation without the surgeon attempting the practice. Upon the suggestion of Mr. Maunder, of the London Hospital, in 1867, Mr. Little applied a ligature to the femoral artery for acute suppuration of the knee, with a success sufficient to prove its value; and the late Mr. Moore, of Middlesex Hospital, acupressed the brachial artery with a good result." Dr. Robert Druitt in his article "Inflammation,"† naturally jealous for originality emanating from his own countrymen, says: "Mr. Maunder, of the London Hospital, has tied the femoral artery in several instances of severe inflammation of the lower limb, and has spoken favourably of the results. Mr. Maunder's first case was so treated by him without any knowledge of the American experiences we have referred to, and his results were as satisfactory as those of Dr. Campbell. The late Mr. C. H. Moore also compressed the brachial artery for severe traumatic inflammation of the hand, acting on Mr. Maunder's suggestions, and in that case also the remedy had a very striking effect."

The advantages I claim for the ligature are best shown by a review of the above case. Immediately on the application of the ligature, pain, previously severe, ceased; and with this cessation sleep and appetite returned. On the following day the countenance was changed from one expressive of physical suffering to that of repose, and in forty-eight hours the man pronounced himself to be "first-rate." Symptoms of inflammatory action, both general and local, quickly subsided—redness paled, swelling disappeared, and the integuments, previously rendered red and œdematous above, about, and below the knee, soon assumed their normal character. On the day of operation

† Cooper's Surgical Dictionary, 1872, vol. ii., p. 65.

Mr. Little and I were not sure whether or not pus was already formed (the man had experienced a slight rigor in the morning), but inclined to the opinion that a small quantity did exist immediately under the skin and middle of the line of the wound, which was healed. We also thought it quite probable that the synovial membrane of the joint had already begun to secrete pus. About forty-eight hours subsequent to operation, both ends of the original wound opened spontaneously and discharged pus, the matter flowing in small quantity, and as though it welled up from the interior of the joint. During this suppurative stage the patient experienced no discomfort, with the exception of slight starting pains for one or two nights, and after the lapse of a few days the discharge of pus, except from the surface of the accident wound, ceased. Another and all-important advantage is, that no blood is taken from the patient; and the subject of these remarks was in no condition to lose an ounce of the vital fluid.

Since then I have tied a main artery twice, with a view to arrest inflammation in a limb, and my colleague, Mr. Reeves, has ligatured the superficial femoral with a similar object. Also, in several instances in which the ligature has been used to stop bleeding, existing inflammation has ceased, and repair commenced. The first of the former was that of a child whose knee-joint had been opened by a burn.

Open knee-joint; suppuration within and without; ligature of the femoral artery; recovery.—A. P——, aged three years and a half (Case 12 in Table of Arteries*), was admitted into the London Hospital, under the care of Mr. John Adams, Feb. 5th, 1869. She had sustained a severe scald by boiling water over the lower part of the abdomen and thighs, and especially of the right knee. She progressed favourably for several weeks, when, on April 8th, the house-surgeon, Mr. Vialls, observed an abscess on the outside of the knee, which broke on the following day.

April 10th.—The patient had recently come under my care (by reason of Mr. Adams's retirement from the office of surgeon). At the site of the abscess a depression in the granulations admitted the little finger into the joint. The cavity contained pus, and an incision made on the inside favoured its flow.

19th.—Suppuration has spread round about the joint, and up and down the limb, and incisions have been made here and there. A drainage-tube was introduced to-day through the joint.

28th.—Limb is more swollen, and two more incisions are made. The discharge is very profuse, and the limb is dressed twice daily in consequence. Drainage-tube removed. Eats and sleeps pretty well.

29th.—The whole limb is now œdematous from groin to toes, and pus can be squeezed out in large quantity at the various openings made from time to time. The child is very exsanguine and emaciated, but takes its food fairly, sleeps pretty well, and has a clean tongue.—3 P.M.: I placed a fishing-gut ligature on the superficial femoral artery at the apex of Scarpa's triangle on the antiseptic plan, everything coming in contact with the wound having been treated with a solution of carbolic acid. The ligature was cut short, and the wound closed by three metallic sutures, and then covered in with layers of lint soaked in carbolic glycerine. The whole limb was carefully wrapped in cotton-wool, and a flannel bandage and splint applied to secure immobility at the knee. A large piece of lint saturated with carbolic glycerine was laid upon the thigh. There is nothing special to record concerning the operation. The vessel was deep by reason of the swollen state of the integuments, and a nerve larger than usual crossed the sheath towards its inner side; the femoral vein was not seen, and not a teaspoonful of blood was lost. The toes looked white and tallowy after the ligature of the vessel.—9 P.M.: Child is asleep; cries when the toes are touched, but moves them freely, they having very much the same appearance as the toes of the opposite member, and are equally warm to the hand.

30th.—3 P.M.: Sitting up; clean tongue; no appetite; strong odour of carbolic acid; much less discharge; toes colder than those of opposite foot. To have six instead of three ounces of wine. To use as little carbolic acid as possible, lest it affect the child's general health injuriously, which it already probably has done.

May 1st.—Clean tongue; has eaten a little meat to-day. Removed the flannel bandage and cotton-wool, and pressed out matter which had accumulated since the operation. Incised a fluctuating swelling, giving exit to pus which existed at the time of operation, on the inside of the knee. The whole limb, excepting the operation wound, dressed from the foot upwards with strips of lint. Wool and bandage reapplied and a back splint adapted.

2nd (only seventy-two hours after operation).—Nurse says the discharge is only a quarter as much as it was formerly. All swelling has subsided. Relishes food.

3rd.—Feeds pretty well. There is a vesication on the heel (from pressure). The little pus discharged from the various wounds is very *thick* in character.

7th.—On exposing the operation wound to-day, it was found gaping and granulating, the sutures being detached by ulceration, but there was no discharge. The child takes milk, wine, eggs, and bread-and-butter freely, but very little meat. There is *not a tablespoonful* of discharge from the whole limb, now only the ninth day subsequent to operation.

It will thus be seen that the operation was markedly successful, the quantity of discharge being reduced to one-fourth. Subsequent to the ligature a small slough from continuous pressure formed on the heel, and I was very anxious about it. To my surprise the slough separated, and the wound healed as readily as though the normal circulation of the limb had not been interfered with. The child made a good recovery, although naturally weakly and the subject of ophthalmia, for which it was treated by my colleague, Mr. James Adams.

Question of operative interference.—With reference to the history of the case up to the time of operation, it is evident that the progress of the condition of the limb was from bad to worse. In the first instance, when the joint was found to have been opened, swelling and suppuration seemed to be restricted to its interior, but soon these limits were overstepped, and pus was found round about the joint on all sides. To give free exit to this, incisions were made, and a drainage-tube was passed through laterally, one end of the tube appearing on the inside of the articulation and the other in the popliteal space, to give exit to matter existing in that locality and to favour gravitation. The original wound on the outside of the joint allowed the matter to escape in that region. In the course of a few days further incisions were necessary above the knee, and on the day before operation matter had burrowed half-way up the thigh and half-way down the leg, and an incision in both situations gave exit to a large quantity of offensive discharge. On the day of operation the whole limb was œdematous, probably as a prelude to, or coëxistent with, further diffuse suppuration.

Now, although the child's general health was fair, still the local symptoms threatened to become worse rather than to improve; and if the former state resulted, not many days would elapse before either hectic or typhoid symptoms would arise, when in the former case proximate safety would be in amputation, but in the latter there would be no hope of recovery. By ligature of the femoral artery I hoped to save both life and limb.

By resorting to the ligature, I of course believed that suppuration would in great measure be arrested, and that amputation or death, necessitated by exhaustion, would be prevented. Also, I am of opinion, of two evils—profuse suppuration or ligature—I had selected the lesser; because I have not that dread of the consequences of ligature of the superficial femoral artery, under certain conditions, which some surgeons profess. I was greatly induced to operate in this case in consequence of an observation made in Mr. Little's case just related. A few hours before Mr. Little operated his patient had had a rigor, and we were led, from certain symptoms, to suspect that suppuration had already taken place in the joint, the original wound being at this time closed. In this suspicion we were probably correct, because, although both local and general inflammatory symptoms declined immediately after the application of the ligature in the most decided manner, still, some forty-eight hours subsequently, the original wound reopened, and the *thickest* possible pus flowed, or rather oozed up, evidently from within the joint. This thick pus was made up of just enough liquor puris to make it a soft solid—a condition due, I thought, to the withholding of fluid from the limb by the ligature on the artery.

---

* The Lancet, Jan. 9th, p. 39.

The two preceding cases will contrast well with the following, in which ligature of the brachial was performed apparently to little purpose only.

Case 18, in Table of Arteries,* was one of acute inflammation of the hand, in a middle-aged female, consequent on a poisoned wound. The whole hand was enormously swollen, with the fingers bent upon the palm. Her temperature was 103°, and the patient was greatly exhausted and had a dry brown tongue. Just above the wrist was a patch of redness, as though suppuration either had already or was about to set in. I tied the brachial artery in the *middle* of the arm, but it is most essential to notice that the effect upon both local and general symptoms was very slight when compared to the alteration for good with ligature on the main artery in the *lower* limb. Pus formed above the wrist, but the palm escaped and the fingers were no longer flexed. The patient died two months later of pyæmia. In the future, should the necessity arise, I would ligature the brachial artery close to the axilla, in order to get above the origin of the *profunda* branches, with the view of still further diminishing the supply of blood to the hand. The arterial anastomoses about the elbow are so numerous that, although the brachial be tied about its middle, its effect upon the blood-supply to the hand will sometimes be too transitory for my purpose, as regards inflammation, but highly conservative with respect to the vitality of the part, as the subjoined show. I tied the brachial for false aneurism, in a young man (Case 16). A good radial pulse existed next day. Also in a man aged sixty-six (Case 13). There was a pulse at the wrist on the third day.

The fourth case known to me is that of a male adult who had sustained an incised wound opening the knee-joint, associated with severe venous hæmorrhage. The bleeding was arrested with difficulty, and violent inflammation of the joint followed. I saw the case in consultation with Mr. Reeves on August 3rd, 1870, and advised ligature of the superficial femoral. The man was extremely exhausted and wasted, and for days no hope of saving him by amputation had been nor could now be entertained. The discharge was most profuse both from the joint and thigh; perspirations copious; temperature 103°; pulse 135; and a large patch of redness had lately arisen over the front and inner side of the articulation. The benefit derived from the ligature in this case was almost ephemeral. The man ultimately died.

I shall now give you some American experience. I have received, through the courtesy of Dr. G. C. Blackman, of Cincinnati, U.S., a *résumé*, published by him in the Cincinnati *Lancet and Observer* of February, 1868, of the cases of traumatic inflammation treated in that country by ligature of the main artery, and which are well worthy of careful study. I will condense the information that I have gleaned. Up to this moment no one had hinted in any way that the operation had previously been performed. It was utterly unknown in this country. It appears probable that the femoral artery was ligatured for wound of the knee-joint, first, by Henry U. Ouderdonk, M.D., in June, 1813; and that the patient was cured. A similar case was so treated by Dr. David L. Rogers, of New York; and in this instance "the man got well by the twenty-fifth day." Dr. Rogers also refers to a case of compound dislocation of the ankle, in which Dr. Mott tied the femoral artery; but the patient died of tetanus. Dr. Rogers is of opinion that "the danger of mortification from defect of circulation is less than might be supposed" (and that has long been my opinion). A lad, sixteen years old, was the subject of a most severe and extensive gunshot wound of the arm. The brachial artery was ligatured high up, and although little hope was entertained of saving the arm, to the astonishment of all who saw the case there was merely sufficient inflammation in the wound to produce healthy suppuration and granulation. He recovered rapidly." Dr. H. F. Campbell, of Georgia, speaking from personal experience of six cases, is also a strong supporter of the principle. Dr. Daniel F. Wright, formerly of Winder Hospital, Richmond, records a case of gunshot wound of the thigh, followed by hæmorrhage, and treated by ligature of the femoral at the apex of Scarpa's triangle. "The injured limb was for some days slightly colder than the other, notwithstanding which the condition of the wound commenced improving from that day." A second case was one of gunshot wound of the middle finger, requiring amputation. Gangrene set in, and spread rapidly; hæmorrhage occurred twice, and then the brachial artery was ligatured in the lower third of the arm. Improvement in the wound commenced at once. A third case is one of gunshot wound of the thigh, followed by spreading gangrene and repeated hæmorrhage. The femoral artery was tied at the apex of Scarpa's triangle, and "the wound healed more rapidly than any lesion of such extent that I have ever witnessed." Two other cases are recorded by Dr. Wright, but were not immediately under his care. The brachial artery was tied in both instances "with a result exactly similar to that in the cases already detailed." Dr. Wright remarks: "In the five cases witnessed by myself, and in the six cases reported by Dr. Campbell, we have this uniform result—that, immediately from the date of ligation, large tumefaction has been superseded by recovery of the original contour, fetid ichorous discharge by laudable suppuration, and phagedænic gangrene by vigorous granulations, resulting in rapid separation of the eroded tissues. ......In all the instances I have given, though the ligature resulted in curing the gangrene, it was not resorted to for that purpose, but for that of arresting hæmorrhage. In the present state of professional opinion it would be bold surgery, savouring perhaps of rashness, to tie the brachial artery for gangrene of the hand, or the femoral artery for phagedænic erosion in the calf of the leg; though my friend Dr. Campbell does not stop short of advocating this very procedure." Also Dr. D. L. Duvall remarks that, in a paper published at Richmond by Dr. S. P. Moore, Surgeon-General of the Insurgent States, the author stated "that he had performed operations on patients whose limbs, after being wounded, presented all the indications of rapidly approaching gangrene from inflammation, when, fortunately for the patient, extensive hæmorrhage ensued, which necessitated the ligature of one or more of the large arteries of the limb, and, to his great surprise, rapid improvement began and the patient recovered." Velpeau too appears to have given this method of combating inflammation his consideration, and in the American edition of his great work on Operative Surgery (vol. i., p. 649) says:—"As compression of the arteries moderates, and even arrests, the circulation in the organs situated underneath (beyond?), it seems at first sight to constitute an excellent remedy in congestions, engorgements, and acute inflammations of all kinds. It is therefore somewhat surprising that physicians should, for so many years, have omitted to make use of it under this point of view. At the present time (1839) the mind appears to take another direction; and compression of the arteries, if we are to believe its partisans, should become the sovereign remedy in convulsions, epilepsy, inflammations of the limbs, &c."

AN

INQUIRY INTO THE CONDITION OF FIFTY-ONE CASES OF LITHOTRITY IN ELDERLY ADULTS, MADE AT PERIODS OF ONE OR TWO YEARS AFTER OPERATION.

By Sir HENRY THOMPSON,
SURGEON EXTRAORDINARY TO H.M. THE KING OF THE BELGIANS;
EMERITUS PROFESSOR OF CLINICAL SURGERY IN UNIVERSITY COLLEGE;
LATE SURGEON TO THE HOSPITAL.

In The Lancet of April 3rd I reported the results of my last 100 stone operations (lithotomy and lithotrity) on adult patients averaging 63½ years of age, amongst whom there were 6 deaths, and consequently 94 recoveries. Mr. Thomas Smith made an inquiry in the following number of the journal relative to the condition of the patients on whom *lithotrity* had been performed, at any period not less than twelve months after the procedure, with the view of ascertaining whether the results of that operation were permanent. Such an investigation I thought desirable, and promised to make it; for although the general results must be well known to myself, I had never applied an exact or numerical test in order to determine them.

I have therefore sought, by writing and personal interviews, to obtain information of the present state in all those cases of this series in which the operation of lithotrity was performed more than twelve months ago—that is, between December, 1872, when it commenced, and May, 1874. Consequently the time after operation is much longer than that which Mr. Smith suggested, for while the last case was treated fully twelve months ago, more than two years and a quarter have passed since the first of the series was operated on.

---

* The Lancet, Jan. 9th, p. 39.

I find that between the dates named—a period of about seventeen months—I performed lithotrity on 53 patients, of whom two died, leaving 51 cases of recovery. The mean interval between the date of operation and the present report of condition, for these 51 cases which are the subject of inquiry, is, therefore, about twenty months instead of "one year." An examination of these cases, given in a tabular form below, shows that respecting six patients I have been unable to obtain the information required; but the weight of such evidence as exists relative to these is greatly in favour of their being better and not worse than the average, since their mean age is only fifty-four years, nearly ten less than the mean of the whole series. As I am compelled to omit these from my reckoning, I believe that my report is less favourable to lithotrity than it ought to be.

The number of individuals, then, of whom I have precise information is 45, averaging about sixty-four years of age. Of these, 11 have since died. The causes, certified by their medical attendants, were—2 of organic heart disease; 1 of malignant disease; 1, at eighty, of natural decay; the other 6 of urinary disorders and advanced age together (the mean age being sixty-six years). All but one of these latter were individuals who for several years had passed no urine except by catheter, who owed their lives solely to surgical art, and who without it must have died miserably some years before. The prolongation of life had been entirely due to the improved modern means of mechanically removing retained urine and accumulated phosphatic deposits. Of the 45, 34 are living still; 28 of them enjoying good health and active existence, at a mean of sixty-three and a half years of age. The other 6 have some signs of recurring calculus, 2 having had a newly formed calculus removed; all are well but one of these, who is in bad health and suffers much.

I think I may leave these figures to speak for themselves. I shall make one observation, however, which, although a very natural one, does appear not to receive the consideration which I think it deserves. Supposing that these 53 cases of lithotrity (including 2 deaths with 51 recoveries) had been cut instead of crushed, how many fatal cases would have followed the operation? Their average age being sixty-three, 14 deaths would not have been a bad result, somewhat better than published tables offer us.* But after these operations, mainly done in 1873, only 11 deaths have since occurred *up to the present date*. And even if we were to reckon all these as deaths resulting from the operation, although, as may be seen below, they were quite unconnected with it, we still should have a total of recoveries larger than after lithotomy. There is, however, much reason to believe that the few examples of chronic cystitis with recurring phosphatic deposits, subsequent to lithotrity, occur generally in those feeble and diseased persons to whom lithotomy is most commonly fatal. The fact is, that almost all those patients whose subsequent troubles remain, and who, to superficial observers, appear to discredit lithotrity, do in reality owe their existence to the operation, and are trophies of life absolutely saved by it.

Thus it is that lithotrity, as I have observed, has created a new set of cases—men who, until the process was brought pretty nearly to its present perfection, never lived. Respecting them I should like to write the results of my experience, and hope ere long to do so. They are men whom lithotrity keeps alive—who, thanks to the ease and safety with which a small and newly formed phosphatic calculus can be crushed, go on for years to live and even to be active. These cases have to be kept apart from other cases of stone, because it would invalidate any inference from numerical statements were a surgeon to reckon as a "case of lithotrity" each time, perhaps twice a year or more, he removed a calculus from such a patient, although it might not always necessarily be very small. But it is not to be forgotten that before the time of lithotrity there was no adequate help for such a patient except by the cutting operation, and many such died miserably with bladders filled with phosphatic material.

I am very glad to have made this inquiry, although it has entailed no little pains and labour; since I venture to hope that it may prove to be, not merely a new, but also a useful contribution to our knowledge respecting lithotrity.

1. A gentleman aged thirty-six; operation, Nov. 1872; uric-acid calculus. I have no knowledge of the address. He made an excellent recovery; and I should, at his age, have probably heard more of him if his health had not continued good.

2. A gentleman aged seventy-five; operation, Dec. 1872; phosphatic calculus. In May, 1875, Mr. Gardner, of Gloucester-terrace, reports to me this patient in his usual health.

3. A gentleman aged sixty-nine; operation, Jan. 1873; uric-acid calculi. This patient, who was under the care of Mr. Newton of Upper Wimpole-street, writes me (June, 1875): "I am in perfectly good health, and have no uneasiness or feelings that lead me to suppose I have any stone in my bladder now."

4. A gentleman aged sixty-five; operation, Jan. 1873; phosphatic calculus. Mr. J. H. Bartlett, of Notting-hill, writes me that this patient had no further symptoms of calculus, and that he died of heart disease three months after.

5. A gentleman aged sixty-eight; operation, Jan. 1873. This gentleman had for many years passed all his water by catheter. His life had been prolonged, with very advanced prostatic disease, by great care and frequent removals of phosphates as they formed. He died, his urinary organs being quite worn out, with extensive sacculation of kidneys and ureters, in December of the same year.

6. A gentleman aged fifty-one; operation, Feb. 1873; uric-acid calculus. Mr. Allen, of Milner-square, Islington, writes me (May, 1875) that this patient is perfectly well.

7. A gentleman aged thirty-six; operation, Feb. 1873; uric-acid calculus. No return, and is perfectly free from symptoms at present.

8. A gentleman aged sixty-four; operation, Feb. 1873; phosphatic calculus. This patient had always passed all his urine by catheter. He had no return of his stone. He became insane, and used the instrument very carelessly. In January, 1875, I was called to see him with severe extravasation of urine, resulting from injury, of which he shortly after died. I saw him with my friend Dr. Murchison.

9. A gentleman aged sixty; operation, Feb.–March, 1873; phosphatic calculus. I heard from this gentleman a few days ago (May, 1875). He is in excellent health, and is leading a very active life.

10. A gentleman aged sixty; operation, March, 1873; uric-acid calculus. Dr. Manson, of Chesterfield, writes me (June, 1875) that this patient "remained quite free from any symptoms of recurrent calculus to the day of his death, which resulted from typhoid fever in December, 1873. He was perfectly satisfied with the result of the operation."

11. W. C——, aged sixty-seven; operation, March, 1873; uric acid; treated at University College Hospital. For many years he has passed small uric-acid calculi; and, having recently had one in his bladder which he was unable to expel, it has been successfully crushed for him in the country.

12. A gentleman aged seventy-one; operation, April, 1873. Writes me (May, 1875) that he continues quite well.

13. A gentleman aged sixty-seven; operation, April, 1873; uric acid. Recently seen by myself, he is performing his duty as a member of Parliament, and enjoys excellent health and strength.

14. A gentleman aged sixty-one; operation, April, 1873. I have just seen him. He is in perfect condition as regards his bladder. His stone was a large uric-acid formation. His medical attendant, Mr. Leppington, of Great Grimsby, writes me that "he has had no symptoms of any return of vesical mischief."

15. A gentleman aged fifty-nine; operation, April, 1873; oxalate-of-lime calculus. He was quite well six months ago, but I have not his address, and have failed to find him.

16. A gentleman aged seventy-nine; operation, April, 1873; uric acid. Had no return of his calculus, and died about a year afterwards of some other malady, apparently from natural decay.

17. W. B. H——, aged sixty-three; operation, May, 1873;

---

* I may refer to my own table of 1827 cases, collected with great care, among others, as supporting this view. "Lithotomy and Lithotrity," 2nd edit., p. 142.

uric acid. Treated in University College Hospital successfully, and his present address and condition are unknown.

18. A gentleman aged sixty-seven; operation, May–June, 1873; large phosphatic stone. Writes me (May, 1875) that he is perfectly well, and better in health than for many years.

19. A gentleman aged sixty; operation, May–June, 1873; large uric-acid calculus. Dr. Evan Jones, of Aberdare, writes to inform me that the patient had rigors in September, and signs of blood-poisoning; no abscesses; and died comatose Oct. 23rd. He had left me in fair condition at the end of June, with some suspicion that the kidneys were not sound.

20. J. W—— (University College Hospital), aged fifty-four; operation, June, 1873; phosphatic calculus. Has long passed all his urine by catheter. Having just written to ask how he goes on, he replies that he was quite well for a long time after operation, but he begins to have signs of some phosphatic formation and wishes soon to be examined.

21. J. W——, aged thirty-six; operation, June, 1873; uric-acid calculus. Treated successfully in University College Hospital, and his present address and condition are unknown.

22. A gentleman from the Brazils, aged fifty-six; operation, June and July, 1873; very large phosphatic calculus. One of the most formidable cases I ever had. He made a most excellent recovery, always, as before the operation, passing all his urine by catheter. He came to me last summer (two years after operation), and I removed a small phosphatic formation which had been developed, and he left me as well as ever.

23. A gentleman aged forty-one; operation, July, 1873. I have just seen this patient; he has enjoyed fair health, and has had no return of his malady. The stone was originally oxalate of lime, and he is subject to irritation in the urinary passages and occasionally to orchitis. He leads an active life.

24. A gentleman aged seventy-seven; operation, July, 1873; uric-acid calculus. In excellent health for his age. No return of his malady. Uses a catheter twice a day, and is under the care of Dr. Jackson of Southsea.

25. A gentleman aged sixty-two; operation, Oct. 1873; phosphatic calculus. Had long passed all his urine by catheter and at short intervals. I removed a phosphatic calculus of considerable size, the result of constant cystitis; but he died exhausted from incessant catheterism about a year after.

26. A gentleman aged sixty-five; operation, Aug. 1873; uric-acid calculus. Seen again in the latter part of the year. Recovery perfect, but have not the address, and cannot learn any later particulars.

27. An American gentleman, aged sixty-seven; operation, Aug. 1873; phosphatic calculus. He wrote me in the following year that there was no return whatever of his complaint.

28. A gentleman aged sixty; operation, Aug. 1873; large uric-acid calculus. I cannot learn anything of this patient.

29. A gentleman aged seventy-seven; operation, Aug. 1873; uric-acid calculus. I have just seen this patient (June, 1875). He has had no return whatever of calculus symptoms, and is passing his catheter three times in the twenty-four hours on account of inability to empty his bladder from enlarged prostate. He is enjoying excellent health.

30. A gentleman aged sixty-seven; operation, Aug. 1873; uric-acid calculus. This patient has not been much relieved. He passes his urine chiefly, if not altogether, by catheter, and, in spite of all treatment, phosphatic matter forms and must be removed.

31. A gentleman aged fifty-six; operation, Nov. 1873; a phosphatic calculus. He had no return of it. Mr. Pearson, of Manchester, writes me that he died of malignant disease in January last.

32. A gentleman aged seventy-eight; operation, Nov. 1873; uric-acid calculus. His medical attendant, Mr. Hicks, of Easingwold, writes me (June, 1875): "The patient has been perfectly free from vesical troubles ever since."

33. A gentleman aged seventy-six; operation, Nov. 1873; uric-acid calculus. Have just seen him (May, 1875); he has had no return whatever of his complaint.

34. A gentleman aged seventy-two; operation, Nov. 1873; oxalate of lime. I saw this patient a month ago (May, 1875). He is in perfect health, and has had no return whatever of his complaint.

35. A gentleman aged sixty-three; operation, Nov. 1873; uric-acid calculus. His medical attendant, Mr. Robert Parker, of Malpas, Cheshire, has just written me (June, 1875) that this patient is "feeling as well as ever he did in his life."

36. A gentleman aged seventy; operation, Dec. 1873; He made a most excellent recovery; left me a hale and hearty man, and I have no doubt is quite well, but I have no clue to his address. I believe he is living in Dundee or its neighbourhood.

37. A gamekeeper at Balmoral, aged sixty-one; operation, Dec. 1873; a phosphatic calculus. He has just written me (May) that he "is keeping well and able for his duty."

38. A gentleman aged sixty-four; operation, Jan. 1874; a large phosphatic stone. Seen with Dr. Holman, of Reigate. Had not emptied his bladder some time before operation. Still uses his catheter. In good health, and has no return of his malady.

39. A gentleman aged sixty; operation, Feb. 1874. This was a uric-acid stone of unusual size, and the difficulties were remarkable. I saw the case constantly with Mr. Blaker, of Brighton. He had long-continued troubles afterwards from inability to pass urine by his own efforts and frequent catheterism. He has slowly improved, and is now in a comfortable condition, with no return of stone formation.

40. A gentleman aged sixty-one; operation, Feb. 1874; a uric-acid stone. I have lost sight of him, and cannot learn his address.

41. A gentleman aged seventy; operation, Feb. 1874. A uric-acid stone, complicated with advanced disease of the bladder. The former was easily removed, but no improvement took place, and he died of the latter about six months after.

42. A gentleman aged sixty-two; operation, Feb. 1874; a uric-acid stone. Called on me May, 1875. In excellent health; no reappearance of stone symptoms. Occasionally under the care of Dr. Macdonald, physician to the Duke of Argyll.

43. A gentleman aged sixty-seven; operation, Feb. 1874. Died suddenly of mitral disease about ten days after the stone, mixed oxalates and urates, was successfully removed.

44. A gentleman aged seventy-eight; operation, March, 1874; phosphatic calculus. Has many years passed all his urine by catheter, and had had a stone removed in 1870; the second in 1874, after which he lived about five months.

45. A gentleman aged sixty-six; operation, March, 1874; very large uric-acid calculus. This gentleman has just written me (June, 1875): "I am well pleased to inform you that I have been very well indeed until the latter end of March." He adds that he has lately had a little irritability of the bladder, which has passed off.

46. A gentleman aged seventy-two; operation, March, 1874; uric-acid calculus. Seen with Mr. Sibley, of New Burlington-street. Is now (June, 1875) in perfect health; no sign of his malady remaining.

47. A gentleman aged fifty; operation, March, 1874; a uric-acid stone. Has been in excellent health since. In January last he passed a small uric-acid calculus per urethram. He is now living at Antwerp, and is quite well.

48. A gentleman aged sixty-five; operation, April, 1874; a phosphatic calculus. This patient had for many years passed all his water by catheter, frequently doing so as often as twelve to fifteen times in the twenty-four hours. He has been quite well until lately, and has just called (June, 1875) to inform me that symptoms have reappeared. I find a re-formation of phosphatic matter, which I shall have to break up and wash out. Otherwise his health is excellent.

49. A gentleman aged sixty; operation, April–May, 1874; uric-acid calculus. He called on me in February last, in excellent health, and without any symptoms of his old complaint, and walking several miles daily.

50. A gentleman aged sixty-eight; operation, May, 1874; large uric-acid stone. Dr. Lambert, of Sunderland, writes (June, 1875) his "condition at the present time is perfectly satisfactory."

51. A gentleman aged sixty-one; operation, May, 1874; uric-acid calculus. Dr. Helsham, of Brixton-road, writes, in May, 1875, that this patient is travelling on the Continent in perfect health.

Wimpole-street, W.

ON THE

DYNAMICAL ORIGIN OF ANIMAL HEAT IN ITS RELATION TO THE TEMPERATURE ALTERATIONS OBSERVED IN CERTAIN INJURIES AND DISEASES OF THE NERVOUS SYSTEM.

BY C. A. RAYNE, M.B. LOND.

IN a letter published in THE LANCET of Sept. 26th, 1874, I called attention to a mode of origin of animal heat which had been till then unrecognised, or, at any rate, had not received that amount of attention which its importance seemed to require. In that letter it was shown that the whole of the mechanical energy originating in the contractions of the heart, must of necessity be converted into heat within the body; and that this heat, far from being a despicable item, as might have been supposed, amounted in quantity (in a human adult of average development) to as much as would be required to raise four pounds and a half of water from freezing to boiling point in twenty-four hours —that is, to about *one-tenth of the whole amount of heat* produced in the body. Further, it was suggested that this fact might have numerous important bearings, especially in regard to the relation which frequently subsists between cardiac, arterial, and capillary tone and temperature.

It will be at once evident, without much consideration, that the amount of animal heat produced in this way must be far more immediately and readily susceptible to fluctuation than that produced in any other way, and that the effect of such fluctuation will immediately be made manifest in local or general alterations in temperature. The subtraction of such a large proportion in the available supply of animal heat as one-tenth, or even much less, would lower the balance of temperature several degrees, whereas its addition would send it up to an almost corresponding extent. How far other modifying conditions might in time arise, especially should the abnormality be long continued, to restore more or less the normal equilibrium, it is difficult as yet to say, but that they would do so to some extent is probable.

We have now to inquire into the conditions which would lead to excess or diminution in the supply of this mechanically originating heat, both locally and generally. As it has its origin in the cardiac muscular energy, the *whole* of which, and neither more nor less, undergoes the conversion (this is capable of distinct *mathematical* proof), it will be sufficient to inquire into the circumstances under which *this* is increased or diminished.

(1) By agencies acting directly upon the heart itself. In this category must be specially named the stimulating effects of any irritation of the cardiac *sympathetic* branches and the depressing effect of irritation of the pneumogastric.

(2) By alteration in the resistances to the circulation, local or general, and the excess or diminution of heat will be locally manifested, where the increased or diminished resistance occurs. That the force of the normally-nourished heart increases, *pari passu*, with the resistance to be overcome is a sufficiently well-known fact, familiar instances of which are afforded in the hypertrophy which occurs in valvular and general arterial disease. What I wish specially to direct attention to, however, is the marked effect upon the resistance to the passage of blood produced by alterations in the calibre of the vessels through vaso-motor nervous agency. The resistance to the passage of a fluid, such as water, through a tube increases with the diminishing diameter of the tube (equal quantities of fluid passing in equal times) in the enormous proportion of the fifth power of that diameter.[*] Thus, if we diminish the diameter by one-half we increase the resistance (and the developed heat is directly proportionate to the resistance) *thirty-two times*.[†]

I have lately had some opportunities of investigating certain of the phenomena of tetanus which bear upon this subject, with results which appear to be in accordance with these views. The disease is not a very common one, especially in a provincial hospital, and many opportunities of observation do not usually fall to the lot of the same person. I would therefore take the liberty of suggesting to others that it is a matter of much importance, in this and in other diseases or injuries of the nervous system (especially the upper part of the spinal cord), to ascertain in a sufficient number of cases the *exact temperature range*, taken at short intervals throughout the course of the affection, certain details as to the *action of the heart*, and the *characters and variations of the pulse* from day to day.

To these points in the semeiology of tetanus, I will briefly refer.

(1) *The temperature* is, I believe, invariably found to be raised during at least some part of the course of the disease. This has been so in all the cases which have come under my own notice. The elevation is by no means uniform, but appears to bear a distinct relation to the frequency, duration, severity, and general character of the muscular spasms. During a long-continued and severe general spasm, it is by no means uncommon to get an elevation of 1° to 2° Fahr. over the preceding interval of rest, and this notwithstanding a semi-asphyxiated condition (shown by general superficial duskiness) and consequent impaired oxygenation. In an ordinary case the temperature ranges from 100° to 103° or 104°, but it is not unusual for it to rise much higher, and it has even been recorded as high as 112° (Wunderlich).

(2) *The heart's action* appears to be greatly exalted, and especially so during the paroxysms. The frequency of contraction may be even doubled, whilst at the same time the force is much increased, as estimated by the impulse and the intensity of the first sound. In the later exhaustive stages of the disease the action becomes necessarily much weakened.

(3) When we consider that the vaso-motor nervous centres are situated[*] in the upper part of the spinal cord, in the very midst of the intense nerve action going on there, it would *a priori* be thought extremely probable that they should, to a greater or less degree, participate in the disturbance. And we have direct evidence that this is actually the case in the *condition of the pulse*, both at the wrist and elsewhere. This is frequent, *small and hard*, and especially so during the attacks of spasm (in the later exhaustive stages of the disease it becomes soft), showing that the arterial muscular coats are in a condition of extreme tonicity, so that the expansion of the arteries is completely resisted, notwithstanding the increased force and number of the cardiac contractions, and consequent blood pressure within. It is further manifested by the blanched aspect of the face and surface generally at the commencement of a spasm, and before the duskiness consequent on impaired respiration has had time to show itself. The *dilatation of the pupils*, which is almost constantly present, also points to sympathetic irritation.

There are thus present the very conditions which are required to increase *very largely* the production of heat directly from mechanical energy. The increase will be directly proportional to the increased resistance to the passage of blood through the vessels generally, and this, as has been shown, is influenced to an extreme degree by their diameter. But also the mechanical action of the muscles generally will tend still further to impede the circulation, and it is certain that a large proportion of the energy which they evolve will be directly converted into heat—i.e., exactly so much and no more as is not manifested in work produced external to the body of the patient.

The elevation of temperature in tetanus is usually ascribed *directly* to "excessively active calorification consequent upon the greatly increased destructive assimilation which is going on.[†] That it is in some measure due to this appears probable, especially in those comparatively rare instances in which, death not having taken place by asphyxia, there is extreme tissue exhaustion and consequent proneness to rapid destructive metamorphosis. And it is probably in these cases only (as in certain other rapidly exhaustive diseases), and towards the end of life, that such excessive temperatures have been recorded, and that a small post-mortem rise has even been observed. It becomes, however, now evident that there is another and a very important factor concerned in this heat production, and that it is at least possible completely to account for it in the earlier sthenic stages of the disease, and throughout in the acute and rapidly fatal forms, without calling in the aid of immediately preceding chemical change at all. The remote source of the heat will, however, no doubt still be chemical, though its immediate source is mechanical. Possibly some therapeutic indications might be deduced from the evident implication of vaso-motor centres (themselves largely under the control of drugs such as belladonna, nitrite of amyl, &c.), and some of the intractability of the disease may be found to be due to complications of this nature, which may be more amenable to treatment specially directed towards them.

---

[*] For this and other calculations I am indebted to the kindness of Professor W. C. Unwin, of the Indian Civil Engineering College, Cooper's-hill.

[†] It is not to be supposed that the increase is actually so great as this in the body, for the *flow of liquid* would of course be much reduced.

[*] See Carpenter's Physiology, seventh edition, p. 281.

[†] See Niemeyer's Medicine, translated by Humphreys and Hackley, 1871, vol. ii., p. 351.

The pyrexia of tetanus is interesting as affording an instance of elevation of temperature pure and simple, uncomplicated by conditions of toxæmia, as in the fevers. It is worthy of note that many of the concomitants of so-called fever are here absent (so much so that the disease is usually called non-febrile); they may therefore be presumed in other cases not to be due directly to elevation of temperature.

In alcoholic stupor, a condition of things is observed in many respects exactly the reverse of what is seen in tetanus. A young and robust man, a soldier, was lately admitted into the Radcliffe Infirmary, under the care of Dr. Acland, in this state. He was quite unconscious, but could be partially roused when loudly spoken to. The pupils, contracted to the size of pins' points, the feebly acting heart and soft relaxed arteries, all pointed to the semi-paralysed condition of the sympathetic and vaso-motor nerves. The temperature in the axilla, after being in bed some hours, was 95°. He was then partially roused as far as possible, and kept so for a few minutes. The pupils immediately underwent considerable dilatation; the pulse at the wrist recovered to some extent its tone, and at the end of the interval the temperature had slightly but quite perceptibly risen.

The remaining class of cases to which I desire briefly to direct attention, as being probably more or less connected with the question of the mechanical origin of heat, have always attracted a great deal of attention and excited much speculation. I refer to the *temperature effects of lesions of the upper part of the spinal cord.* These cases are, however, extremely difficult to deal with. No one who looks over the mass of literature which has been written upon the subject can but be struck with the great discrepancies of statement put forward by different observers. The causes of temperature alterations in these cases are no doubt often complicated and numerous, and no one cause is sufficient. But it cannot well be doubted by anyone who considers the subject, that, in the mechanical origin of animal heat, capable of being so readily and largely influenced by vaso-motor agency, we have a factor which *must* have in many cases very great influence, and the consideration of which, in attempting to arrive at their solution, ought by no means to be neglected.

It will be advisable to point out what might *a priori* be expected to be the temperature effects of vaso-motor injury after elimination of complications, such as shock, secondary inflammations, &c., and then to see how far such effects correspond with the facts of recorded experience.

1. When some part of the vaso-motor tract is so injured, *without irritation,* as simply to paralyse locally the vessels of a part, we shall get dilatation of those vessels with consequent increased afflux of blood, more or less active according to the state of the heart (the nerve-supply of which, it must be remembered, may be implicated in the injury). In this way the heat from the interior will undergo greater surface distribution; and it is not improbable that there may be increased tissue oxygenation for a time—that is, so long as a previously accumulating store of effete products exists, ready to take advantage of the excess of oxygen brought by the increased amount of blood. We may thus get a surface elevation of temperature, which may even mount above the normal blood heat. It is certain, however, that diminution will eventually supervene; for in addition to the mechanically developed heat being greatly reduced, the blood generally, from greater exposure, will undergo more rapid cooling, and the excess in oxygenation will also gradually cease.

Clinical evidence supports this view. Mr. Hutchinson states* what he considers has been hitherto overlooked—viz., that the increased temperature in vaso-motor paralysis is *only temporary,* and that subsequently it is diminished, and that in all cases of paralysis a low state of temperature eventually results. He quotes the case of a man with paralysed cervical sympathetic from injury, in whom the ear of the affected side was eventually always decidedly colder than the other. Tscheschichin also† has observed after section of the spinal cord in various situations a sinking of the general temperature to accompany suppression of vascular activity. No doubt where the nerve-supply is entirely cut off from a part, so that its nutrition fails, the diminished cell-change will contribute to this effect.

2. When the vaso-motor centres are completely paralysed, as by a crush to the upper part of the spinal cord, so severe as completely to destroy them, *without the possibility of irritation,* and thus to produce general vascular paralysis throughout the body, we may expect the same series of phenomena; but in this case the diminution of temperature will be more general and more marked, and will supervene almost immediately.

In a case related by Mr. Hutchinson in the clinical lecture referred to, these conditions existed in a remarkable degree. The patient, with all the symptoms of complete vaso-motor paralysis after crushed cord, and without much shock, had a temperature of about 95° during the whole five days that he survived. In the case of alcoholic poisoning already alluded to the same temperature and vaso-motor conditions existed.

There are other cases, however, which do not so clearly give support to this view; the general evidence indeed on the subject is frequently contradictory and unreliable. It must be remembered that there are many sources of fallacy: the condition of the vessels, as to their true state of paralysis or the reverse, is in some cases open to question; also one part of the vaso-motor nervous apparatus may be paralysed, whilst another, not so easy of observation, may be acting excessively from irritation; or the cardiac nerve-supply may be interfered with in one way or another. The whole subject needs carefully reviewing in the light of more detailed and accurate observation.

3. When the vaso-motor centres are so injured as to lead to their irritation and excessive action, what results may be expected to follow? This is probably by far the most common condition after spinal injury, and is, therefore, the more interesting. For it is far from probable that a spinal crush should be so absolute and complete as quite to destroy, through a considerable tract, the grey centres in its interior, although it may be sufficient to destroy its powers of conduction to parts below. Therefore, when inflammatory irritation supervenes, many of the nerve-cells will be thrown into excessive action, and amongst them no doubt many of those belonging to the vaso-motor centres. In support of this statement I may point out that it is usual in these cases to get evidences of spinal irritation elsewhere, such as pain, spasm of certain muscles, &c., but that where the injury is so great as to produce total vaso-motor paralysis such evidences are rare, as in Mr. Hutchinson's case already mentioned.

Now this vaso-motor irritation will produce more or less general vascular contraction, with, on the principles already laid down, immensely increased resistance to the blood-stream, and a proportionately increased development of heat, as in tetanus. This heat may be expected to develop, not immediately, but gradually, and on the supervention of inflammatory irritation. On reference to cases this supposition will be found to be strictly correct. In Mr. Hutchinson's cases, 1 and 2,‡ the temperature was at first low, with signs of sympathetic paralysis (soft pulse, priapism, &c.); and, as it ascended, symptoms of sympathetic irritation came on. The action of the heart we should expect to be increased, at least in force if not frequency, as appears to be the case.

See, also, experiments of Tscheschichin on the medulla oblongata of a rabbit, quoted by Wunderlich.§ He found elevation of temperature, accelerated circulation, and increased reflex excitability to be concurrent phenomena.

---

* Clinical Lecture published in THE LANCET, May 22nd, 1875, fourth paragraph.

† Reichert's Archiv, 1866, p. 152, quoted in Wunderlich's Medical Thermometry.

‡ THE LANCET, May 29th, 1875.

§ Medical Thermometry, Sydenham Society's Translation, p. 151.

It will thus be seen that there is much probability that, contrary to the views usually accepted, vaso-motor irritation, and not vaso-motor paralysis, is the condition most frequently met with in conjunction with elevation of temperature in lesions of the spinal cord; and that the increased heat is at least largely due to direct mechanical conversion.

A Mirror of HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum, tum proprias collectas habere, et inter se comparare.—Morgagni *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ST. BARTHOLOMEW'S HOSPITAL.

INTENSE AND CHRONIC NEURALGIA IN THE TRACT OF THE RIGHT DENTAL AND AURICULO-TEMPORAL NERVES; OPERATION; RECOVERY.

(Under the care of Mr. Savory.)

For the notes of the following interesting case we are indebted to Mr. F. W. Strugnell, house-surgeon.

George P——, aged fifty-three, a thin, spare man, with grey hair, looking older than his years, was admitted into Kenton ward on March 20th, 1875. For the last seven years the patient had suffered from intense neuralgic pains in the face, occurring at irregular periods. The attack of pain commenced by a sensation of twitching in and near the first bicuspid tooth on the right side of the lower jaw. This was very quickly followed by lancinating pain, very excruciating, extending from this part to the angle of the jaw and upwards towards the right temple, spreading both backwards and forwards. The first fit, the man stated, was brought on by yawning. Eating, drinking (especially cold drinks), talking, or tapping the tooth, would cause an attack, but not always. In the early morning the fit most frequently occurred, when at breakfast. To take food the patient lay on his back, took very small morsels, and ate very slowly on the left side of the mouth. The more frequent the attacks the less severe they became; sometimes they would occur two or three times a day, occasionally there might be an interval of twenty-four hours between them. The twitching pain in the tooth and about it was permanent. At first the pain commenced in the last molar tooth, which was extracted; but the pain then shifted to the next, and each time a tooth was removed the pain was referred to the adjacent one. Several drugs had been employed, most of which relieved for a short time, some not at all.

When an attack occurred, the patient sprang up, his face became red, his eyes suffused, and there was an expression of intense agony in his countenance; he seemed to lose all command over himself, rushed about the ward, with his hands at one moment tightly holding his jaw, at another tearing at his hair, and he had evidently lost control over his actions. The fit subsided as suddenly as it began, and the poor fellow sank into his chair exhausted. The length of time an attack lasted did not exceed a minute. His previous history was good. He had had rheumatic pains in the knees and back for some years, but had felt nothing of them since the present affection.

On admission the patient was given bromide of potassium, and afterwards chloride of ammonium in twenty-grain doses, with seeming benefit for a short while. He slept well at night, the fits not occurring during sleep.

As the patient did not improve, and begged that something might be done, Mr. Savory decided, in consultation with his colleagues, to trephine the lower jaw and divide the dental nerve. This was done on the 21st of April. Two incisions, meeting below at an angle, were made in front of the masseter muscle on the right side of the lower jaw, and the triangular flap of skin raised; the bone was trephined. and a piece about the size of a sixpence removed; the dental nerve and artery were thus exposed in the horizontal diameter of the circle. Mr. Savory then cut out about one-third of an inch of the nerve.

For three or four days after the operation the patient still felt the twitching sensations, which on the second day were rather severe, but no fit occurred. Nine days after the operation he was able to eat an egg, and on May 2nd was allowed fish. He was discharged on May 16th, quite well, with no pain of any kind. On May 29th he was still perfectly free from any pain.

MIDDLESEX HOSPITAL.

CANCER OF OVARIES AND PERITONEUM AND UMBILICUS; COMPRESSION OF THE COMMON BILE-DUCT; JAUNDICE; DEATH.

(Under the care of Dr. Liveing.)

For the notes of the following case we are indebted to Mr. Arthur Tomes, house-physician.

Harriett B——, aged fifty-nine, was admitted into Northumberland ward April 23rd, 1875. She was emaciated, slightly jaundiced, had a furred tongue, was constipated, and suffered with the following symptoms:—Pain in abdomen, not localised, but general; loss of appetite; nausea and vomiting of bilious matter, and on one occasion of a little bright blood. The history of the illness was that three months before she caught an influenza cold; a month later jaundice appeared, preceded by great pain in the abdomen; this pain became more or less continuous, increased by food, and accompanied by frequent nausea and retching; the bowels had been sluggish.

On admission, no tumour could be found in abdomen; liver dulness was about normal; tenderness over surface of abdomen, especially in right hypochondrium; no enlargement of superficial veins; no varicose veins of lower extremities. The umbilicus was noticed to be hard and *button-like*, and adherent, as though tied down to subjacent structures. Urine (sp. gr. 1022) contained bile, but no albumen. The motions were pale, but contained some bile.

By the 28th the jaundice had become more intense, the pain and vomiting had increased in severity, and the patient was noticed to be continually on her right side.

On May 4th a subcutaneous injection of morphia was ordered to be given when she was in most pain. The uterus was examined per vaginam, and was found to be movable; the cervix slightly nodular; no sign of carcinoma.

In spite of all treatment, the symptoms became more and more aggravated; there was obstinate constipation, which had to be overcome by purgatives and enemata, until the 17th, after which date there was constant relaxation of the bowels, attended with much tenesmus, and a fetid discharge of watery fluid. Her urine was found to contain a little albumen. She died on the 23rd of May.

Post-mortem examination.—On opening the abdomen the liver was seen to extend about three fingers' breadth below the ribs. The parietal peritoneum, notably in the pelvic and iliac regions, presented several minute white nodules, and thickened puckered scar-like patches of cancer. Small white thickened patches of various sizes and shape were met with on each side of the pulmonary pleura, which, microscopically, were found to possess the alveolated structure, enclosing multiform cells, characteristic of cancer. The liver, enlarged and olive-coloured, contained bilious cysts in its posterior part, and the bile-ducts were generally dilated. The hepatic ducts were distended with bile, and were dilated to the size of the forefinger. Gall-bladder shrunken, and its coats thickened; it contained inspissated bile and a number of small gall-stones. The cystic duct was pervious, but the common duct was almost completely constricted at a point two inches from the duodenal orifice, and the probe could be passed through it only with difficulty. The lymphatic glands and tissues in the neighbourhood were all thickened and puckered, and were evidently the cause of the constriction by pressing on the common duct. The right ovary was enlarged to thrice its normal size, hard, and fibrous, presenting the naked-eye and microscopical appearances of scirrhus cancer. Close to it lay another oval mass, the size of a hazel-nut. The left ovary was also enlarged, but softer and more vascular than the right.

Sections of the thickened and dense tissue underlying the skin of the umbilicus presented, under the microscope, infiltration of the corium with cells of an epithelial type, arranged more or less within alveoli. The cells assumed very various shapes, and contained large nuclei. Sections of the lymphatic glands in the hilus of the liver showed also typical spaces containing "cancer cells."

The post-mortem examination and microscopical sections were made by Dr. Sidney Coupland, curator.

DUNEDIN HOSPITAL.

FRACTURE OF TIBIA AND PARTIAL DISLOCATION OF ASTRAGALUS; OPERATION; RECOVERY.

(Under the care of Dr. HULME.)

ROBERT I——, aged thirty-nine, miner, was admitted Sept. 22d from Tuapeka Hospital. When working in a tunnel seventeen months previously, the earth caved in, causing a fracture of the patient's right fibula, and a partial displacement of the astragalus outwards. The skin was inflamed over the projecting portion of the astragalus and walking was very difficult.

On Feb. 8th the projecting portion of the astragalus with about half an inch of the body of the bone was removed by Dr. Hulme. The wound healed favourably, and the patient gradually gained strength in the joint and left the hospital on Jan. 4th, 1874, able to walk tolerably well. He now gets daily employment in a saw-mill.

TRAUMATIC ANEURISM; OPERATION; RECOVERY.

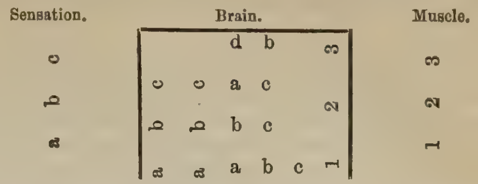
Hugh B—— was admitted March 5th, 1875, with traumatic aueurism of the radial artery. Two months previously he received a wound in the right forearm two inches above the wrist. The wound healed, but shortly there appeared a small swelling, which increased to the size of a duck's egg. The patient was then under the care of a Chinese doctor, who poulticed the swelling and occasionally punctured it with a needle. Dr. Hulme opened the sac and tied both ends of the artery. The ligatures came away on the sixteenth day, and the man was discharged cured on the 29th of the month.

It may be of interest to note that an infusion of bluegum leaves (4 oz. of fresh leaves to a pint of water) has been given by Dr. Hulme, in several cases of diarrhœa requiring astringents, with the best effect. But in cases of chronic dysentery it appears to be inferior to sulphate of copper.

Reviews and Notices of Books.

The Mind of Man, being a Natural System of Mental Philosophy. By ALFRED SMEE, F.R.S. Bell and Sons. 1875.

MR. SMEE has, we think, in this book made the mistake of attempting to compress far too much into a small space. He has laboured to be brief and has become obscure. In the compass of about 250 pages he presents us with a system of mental philosophy, a system of moral philosophy, and a theory intended to show that the action of the nervous system is essentially that of a voltaic battery, or, rather, of a series of voltaic batteries. Each of these subjects would demand a volume in itself, and the result of his efforts is, that the book as a whole wants coherency and betrays its origin in a series of separate papers and lectures delivered or written at various times. He coins an extraordinary number of new terms—"aisthenics," "syndramics," "normics," and compounds of these, till the reader is fairly bewildered; whilst in more than one place he has introduced diagrams, with letters or figures, and with so little attempt at description that they resemble those ingenious cyphers that are unintelligible to all who do not hold the key. This is particularly the case with that on page 181, which, as Mr. Smee holds that by it he can account for all the phenomena exhibited by animals, we here append, leaving our readers to extract what they can out of it.



All the explanation Mr. Smee affords us of this diagram is, that volition or actions through the nerves, marked 1, 2, 3, would depend upon the character of the impression in the respective parts of the combination battery a b, a c, b c, a b c.

The chief objections to Mr. Smee's theoretical nervous combination of man—in which he represents by three spaces the nervous expansion of the skin, ear, and eye, with cords proceeding to (1) an aisthenic centre, containing ganglionic cells that give off branches to (2) the syndramic centre, which again communicates with (3) the aisthenic normic centre, which sends fibres to (4) the syndramic normic, which communicates with (5) the pneuma normic centre, which sends fibres straight to the muscle—are that this plan does not provide for the reflex actions which may take place at the successive planes of Mr. Smee's ganglionic cells; that is to say, at the plane of the sensory ganglia, ideomotor ganglia, &c., whilst it exhibits what certainly does not take place, that the fibres for the muscles emanate directly from the highest centre.

The book absolutely teems with statements that would require a volume for their elucidation and illustration. Thus in one place he observes, that "on a study of the laws of human action we find that the child is born with a will which is unrestrained, and free to act in any manner." Is this so? Has heredity nothing to do with the mode of action? Many of the statements, too, are very loose. Thus Mr. Smee states that an artificial blood-corpuscle may be made by placing a little persalt of iron in animal membrane. Now we can scarcely think that Mr. Smee can really believe that we can thus imitate a blood-corpuscle in any one of its relations, physical, chemical, or physiological. And so, again, in regard to the "voltaic mechanism of the nervous system," we must confess that we are profoundly sceptical of Mr. Smee's views and arguments. We think he mistakes the effect for the cause. We have no doubt that manifestations of electrical disturbance can easily be shown in nerve and muscle and blood, but these are due to chemical changes of varying activity taking place in the several tissues, according as their composition is more or less stable and the supply of oxygen is more or less free. These chemical changes are attended in living nerve with the development of nerve force, the electrical manifestations being entirely secondary and subsidiary phenomena. We cannot admit that the nerve force and electrical force are identical, or that the former can be expressed in such terms as the following:—

> "The most simple idea of a voltaic element in the nervous system would be obtained by a circle of one motor nerve and one sensor nerve, the termination of one end of the sensor nerve being situated in the organ of sensation in the body in aqueous matter in the tissues, and one end of the motor nerve being in contact with aqueous matter in the muscle. The other extremities of the two nerves are inserted in the moist tissue of the grey matter of either the brain or spinal cord, the two connecting nerves being insulated conductors, similar to the wires of our telegraph, except in this respect, that the interior of the nerve-fibres consists of fluid, whilst the connexions of telegraphs are made of metal."

Throughout this chapter the identity of voltaic electricity and nerve force is calmly assumed, though it is as yet an utterly unproven hypothesis. The wonderful disposition of

Mr. Smee to be discursive is exhibited in this chapter to its fullest extent.

Notwithstanding the failings we have noticed in this book, Mr. Smee has managed to make it interesting, and we recommend our readers to get it, if only to exercise their ingenuity. The best bit of work in the whole volume is the index, for which Mr. Smee states in the preface that he is indebted to his daughter, Mrs. Odling, and which is a model of its kind.

Therapeutics and Materia Medica. By ALFRED STILLÉ, M.D. Fourth Edition, thoroughly revised and enlarged. In Two Volumes. Philadelphia: H. C. Lea. London: Trübner. 1874.

MANY English and more American readers will welcome heartily the fourth edition of Dr. Stillé's treatise on therapeutics and materia medica. Its proportions are huge, the two large volumes containing nearly two thousand pages. The pharmaceutical aspect of the subject is subordinated, the therapeutics are given in almost exhaustive detail, the results of modern European research being very fully reproduced. To the account of every drug a history of its use is prefixed, and the information thus given is in many cases of great interest. The work is, indeed, one of which it is not easy to speak in too high terms. The various drugs are grouped according to their actions, and the account of each group is preceded by a sketch of their general properties and modes of action. The additions to the fourth edition bring this work fairly down to the present stage of therapeutics. They comprise in all about 250 pages, and include a chapter on electricity, by Dr. M. J. Grier, of nearly sixty pages, which gives a good and useful account of what is now known on the subject.

We are surprised to find that pepsine is omitted from the present edition, being dismissed from the materia medica with the note that "experience has shown that the notions entertained for a time of its virtues were illusory, and as the history of this preparation has furnished a fresh demonstration that *a priori* conclusions on therapeutics are generally valueless, any account of its preparations and uses appears superfluous." As far as we are aware, there are no published facts which afford sufficient ground for such an abrupt dismissal of an agent still in wide use. That carefully prepared pepsine possesses the alleged property of dissolving albumen is unquestionable, resting upon ample evidence. There can be no doubt that the best specimens of commercial pepsine, prepared both in Germany and this country, possess the same property. In the opinion of many of the physicians of largest experience in this country, good pepsine is of considerable value in the treatment of gastric troubles, at least if we are to judge from the fact that it is still frequently prescribed. Many pepsine preparations are quite inert, both those prepared in this country and in America, but this is hardly sufficient ground for excluding it from the Pharmacopœia, into which, in this country, it was introduced only last year!

The Borderland of Insanity, and other allied Papers. By ANDREW WYNTER, M.D., M.R.C.P. Lond. London: Robert Hardwicke. 1875.

IN these papers Dr. Wynter has, we think, opened up a new subject of research. If we could only get at the "early warnings" which foreshadow brain disease, no doubt in many cases, where there was no hereditary taint, we should be able to ward off the attack, although we may not be quite so sanguine as Dr. Wynter, who says that "the first stage of insanity, where there is no hereditary taint, is far more curable than an attack of pneumonia." Nevertheless we quite agree with him when he says that it is greatly to be regretted that it has been the practice to look upon insanity as a specialty, apart from general medicine, which students are rarely called upon to study. We are glad to see that he treats mental disease as arising from a purely physical cause, and therefore to be attacked by the same means. This being the case, the necessity of educating the general practitioner in psychological medicine is clearly indicated. He it is who is most likely to be informed of the first beginnings of mental alienation, and would be the better able at an early date to stem its advance. Dr. Wynter has, we think, struck a true note when he asserts that brain disease in the convalescent stage is best treated by associating the patient with healthy minds. He objects to such cases being mingled with the mass of asylum patients "sodden with insanity." He thinks that in such cases the family life in the house of the physician is by far the best method of cure, and he justly quotes the good influence of the companionship of healthy minds upon even chronic cases by the known results, both economically and psychologically, of the insane colonies of Gheel in Belgium, and of Kennoway in Scotland, where the insane go forth to their daily labour with the same population in the fields, to the great advantage of the former.

Dr. Wynter pleads, in these pages, for a still further advance in the direction of non-restraint. "We have got rid of the fetters to the body, but the fetters to the mind still remain unnecessarily severe and galling to the tender susceptibilities of the mental convalescent." Here we think he is right, and after a certain period, when all acute symptoms have subsided, "the family life" in the house of a physician is by far the best medicine for the ultimate cure of the patient.

The allied papers are full of striking illustrations bearing upon the happy title chosen for this volume, "The Borderland of Insanity." The discovery of the early warnings of insanity may be called at present unknown ground—a psychological North Pole, in which the diligent explorer is sure to find facts that will amply repay him for his research, and Dr. Wynter has done his share in this volume in furthering the quest.

Ure's Dictionary of Arts, Manufactures, and Mines. By ROBERT HUNT, F.R.S., assisted by F. W. RUDLER, F.G.S. Seventh Edition, completely revised and greatly enlarged. London: Longmans. 1875.

THE appearance within a few years of three editions of so bulky a work as Ure's well-known dictionary is itself a sufficient proof of its value. So well was it compiled and written by the original author—a man of vast knowledge and singular lucidity of thought and language,—and so excellent has been the editing since his time, that the work has for more than half a century retained a leading position among scientific treatises. Mr. Hunt has been assisted by a zealous staff of writers, many of them men of European reputation, and we find that the difficult tasks of addition, excision, and rewriting have in most cases been exceedingly well executed. Comparing the new edition with the old, we find many important additions and improvements. It is sufficient to point to the articles on Iron, Coal, Artillery, Calico-Printing, and Aniline Colours, as examples. The smaller additions and alterations are almost infinite in number, and add very materially to the value of the work.

Absolute perfection in a dictionary of this kind cannot be expected. Omissions and errors can always be detected by the dozen in a closely printed reference work of over three thousand pages, but it would be hardly fair to dwell upon them in so short a notice. "Ure's Dictionary," as it now appears, is a most admirable book; it has no rival, and will not easily be displaced from its pre-eminence.

THE
GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

Session 1875.

MONDAY, JUNE 21ST.

A LETTER was read from the Local Government Board, enclosing a copy of the order recently issued from that department with respect to the qualification of the medical practitioner by whom a certificate is required to be given to entitle a district medical officer to a fee for amputation performed in the case of any pauper, the order removing the previous restriction and extending the qualification in accordance with the principles of the Medical Act.

The communication was ordered to be entered on the Minutes.

The Council then went into committee, and resumed the consideration of the report of the visitors of the examinations of the Royal College of Surgeons of England.

Dr. **STORRAR** referred to the history and position of the College of Surgeons, which he said had always been a body of pure surgeons, and there had been a tacit understanding between it and the Apothecaries' Hall that one should take one part of the examination, and that the other should take the other part. The Act of 1858, however, gave to the members of the College of Surgeons the right to registration. That was not the act of the College, but of the Legislature, and was the result of the bad drafting of a clause. The College never sought the privilege conferred upon it, and was now promoting a Bill to enable it to enter into a scheme for a conjoint examination. When that scheme came into operation, the College would no longer be open to the remarks which had been made respecting its examinations. He was glad to find the College taking the honourable course it was now pursuing. He had often spoken of it in hard terms, but it was really something exhilarating to see the warm breath of liberal common sense telling upon the icy resistance that had long been manifested in that body. It had been in their power to hinder the progress of medical education, it was now in their power to promote it, and henceforth he hoped that the College of Surgeons might be regarded as an advanced body.

Sir W. **GULL** suggested that it would be a great improvement if the students, in their clinical examination in surgery, were taken to the hospitals, where there were numerous cases of accidents, instead of having patients brought to the College.

Mr. **QUAIN** said that every one going to the College of Surgeons was told that he must get a qualification in medicine elsewhere, so that there was no such thing as a person being qualified by the College of Surgeons only. Then it should be borne in mind that the real surgery of the country was in the hands of the *fellows* of the College. There were two diplomas, and one did not necessarily lead to the other. The examinations were quite distinct; and it was not necessary to be a member in order to become a fellow of the College. The fellows were examined clinically in the hospitals, and more extensively on other subjects; moreover, they must be twenty-five years of age, and required two years more study than members. With regard to natural sciences, under the old system a young man came to his school with at least sufficient knowledge to enable him to follow the lectures; but at present they came without a particle of knowledge. A young man had told told him that the greater part of his first year was occupied in getting as much knowledge as would enable him to understand the lectures he was required to attend.

Mr. **MACNAMARA** inquired whether a member of the College of Surgeons in Ireland would require the diploma of the College of Surgeons in England in order to hold the office of surgeon in a country hospital.

Mr. **QUAIN** replied that the hospitals are supported by private contributions, and that the governors make what rules they please.

Mr. **MACNAMARA**.—Would he not be entitled to become surgeon in the army?

Mr. **QUAIN**.—Yes; but he would have to go into the Army School of Medicine and Surgery.

Dr. **THOMSON** said it appeared that the College of Surgeons might grant licences to be registered upon qualifications which, in the view of the Council, were imperfect. The whole effort of the Council had been to make the qualifications complete; and it was clear that every candidate should possess the knowledge which the Council held to be requisite to entitle him to become a member of the profession. The College of Surgeons were no doubt right in paying special attention to anatomy and surgery, but it ought not to neglect any of the branches of knowledge required by the Council.

Dr. **HUMPHRY** said they were told that the surgery of the United Kingdom was in the hands of the fellows of the College of Surgeons; but it appeared that only eleven gentlemen passed the fellowship examination last year. He understood that there was a difficulty in filling even the higher appointments in London with the fellows of the College. The reason was that the regulations requisite for a fellowship were such as to preclude the great mass of the surgeons in England from being candidates at the examination. This was a serious question, and he was glad to have an opportunity of mentioning it. He hoped that such an alteration would be effected as would fully and fairly admit the members to the fellowship examinations. He agreed with Sir W. Gull that the examination for the members as well as for the fellows should be made more clinical.

Sir W. **GULL** said it was hard upon him to be called the Rhadamanthus of the Council; but it was also a reflection upon some other members who failed to do their duty. He (Sir W. Gull) ought not to have to move in the matter of the College of Surgeons; but he should think it his duty to move that special attention be drawn to the incompleteness of the physiological part of the examinations, and the deficiency of the clinical examinations for the membership. He was utterly astonished to hear that the members of the College of Surgeons were not fitted to perform the higher operations of surgery. He had often been astonished at the skill exhibited by them in the most obscure cases, when called upon to act at a moment's notice. They certainly ought to have every facility for acquiring the requisite knowledge. It was the duty of the Council to urge that the clinical examinations should be more complete, so that the country might be better served. The members of the College should all be qualified to perform the higher operations, and the fellowship should not be given for practical dexterity so much as for higher scientific qualifications. In the present day almost as much medicine was wanted as surgery, especially in what was called "conservative surgery." He would strongly urge that the medical and surgical examinations should be henceforth clinical.

Dr. **PARKES** said that the examination at the College of Surgeons was certainly practical, though it did not take place at the bedside, and the same thing might be said of the examination at the Apothecaries' Hall. There were sixteen or twenty patients present, and the examiner asked each candidate in the space of time allowed (ten minutes) to examine a case, and give a rapid diagnosis. It appeared to the visitors that to that extent the test was a fair one.

Dr. **WOOD** said that one of the objects of the clinical examination was to direct the attention of the students to the importance of attending cases in the hospital. Since clinical examinations had been introduced in Edinburgh the students had been far more diligent in attending the visits of the surgeons and inquiring into the cases. He thought that attention should be called to the fact that a member of the College of Surgeons might be put on the Register without having undergone an examination in chemistry.

Dr. **ROLLESTON** pointed out that the Royal College of Surgeons in Ireland had a clinical examination in surgery. With regard to chemistry, he objected to one board accepting the imprimatur of another body. An examination should be thorough in all points before a candidate was allowed to pass.

Mr. **MACNAMARA** dwelt on the importance of due attention being paid to physiology.

Dr. **FLEMING**, as one of the visitors, said that they had thought it sufficient to state the facts they had witnessed.

Sir WM. **GULL** then moved, "That attention be drawn to the incompleteness of the physiological part of the examinations, and the deficiency of the clinical examinations for the membership; also to the total want of any examination in chemistry and materia medica, though these subjects are in the curriculum."

Dr. Wood seconded the motion.

Mr. Quain said it was his duty to call the attention of the College of Surgeons to the recommendations of the visitors of the Council, and there was therefore no necessity for such a resolution. With regard to the clinical examination, all the cases referred to as having been examined at the Royal College of Surgeons in Ireland might have been as easily examined in an ordinary room as in a hospital. It did not, for example, require that a case of hare-lip should be examined when the patient was in bed. As to physiology, the two questions given by the visitors, together with questions given orally, would, he thought, be an adequate test. If the oral questions were not asked the examiner did not perform his duty.

Sir Wm. Gull said that the members of the Council were not sent to it to defend the deficiencies of their own particular bodies, but to represent the interests of the public and of medical and surgical science. He therefore thought that it was Mr. Quain's duty to vote for his motion.

Dr. A. Smith supported the motion. It was possible that the representative of a particular body might omit some point that it was desirable to notice, and the only safe course was to pass a resolution calling special attention to the matter.

Dr. Parkes said the case of the College of Surgeons was not so serious as that of the College of Physicians, and he did not think that any censure was called for.

Sir Wm. Gull.—It is not a censure; it is only calling attention to a deficiency.

Dr. Sharpey opposed the resolution, believing it to be unnecessary, the visitors being of opinion that the examination was well carried out so far as the opportunity was supplied. It was no doubt objectionable that so little reference was made to physiology, but a considerable advance had been made since he visited the examinations with Dr. Parkes some years ago.

Dr. Begbie said he should vote against Sir Wm. Gull's motion, not because he was indifferent to the existence of the defects to which reference had been made, but because he regarded the presence at the Council of the distinguished representative of the College as a sufficient guarantee that those defects would be inquired into.

Sir W. Gull said if the motion were not passed he should move that the resolution with regard to the College of Physicians be rescinded.

Dr. Thomson said that, as one of the minority in regard to the resolution respecting the College of Physicians, he should have been glad to avoid voting for the present motion, believing that no advantage was gained by the Council proceeding in the way suggested; but, in common justice, the one motion having passed, the other ought not to be rejected. Should it, however, be rejected, he was glad to think that there would be an opportunity of rescinding the former motion.

Dr. Humphry opposed the motion, and hoped that the previous one would be rescinded.

The motion was then put and negatived, 8 members voting for it and 12 against.

Sir Wm. Gull said that, on further consideration, he would not move to rescind the resolution respecting the College of Physicians, as it would seem ridiculous to do so. He would rather that the Council should be inconsistent.

The Council then proceeded to the consideration of the report of the visitors of examinations of the King and Queen's College in Ireland, which, after a brief conversation, was ordered to be sent to the College for consideration and remarks.

The next report was that of the visitors to the examination of the Apothecaries' Hall, Ireland.

Dr. Leet said he was glad to find that a large portion of the examinations had met with the approval of the visitors. They stated, however, that the oral examination in anatomy and physiology was confined to osteology. If it was the opinion of the Council that the examination should be more extended, he would undertake to say that it should be done. Dr. Leet proceeded to notice several other parts of the report, especially referring to the remarks on the clinical examination, which was said to be insufficient.

Dr. Wood called attention to various deficiencies pointed out by the visitors. At the clinical examination there were only two candidates, who were both rejected, though the visitors were favourably impressed by them.

Sir D. Corrigan called attention to the mode in which the examiners were appointed. He said they must be shareholders in the corporation; and shares were offered for sale for the purpose of giving a qualification. He read the following advertisement in reference to this subject:—"Apothecaries' Hall. For sale, one Share in the Apothecaries' Hall, Ireland. Offers for it will be received by the undersigned to 31st March inst. This Corporation has latterly been paying dividends at the rate of £20 per share per annum. Cornelius Carleton, 12, Eden Quay, Dublin." It was scarcely to be wondered at, he said, that under these circumstances the clinical examination should be defective.

After some further observations,

Sir W. Gull ridiculed the clinical examination, at which, he said, the candidates were asked to recognise a case of delirium tremens, but were asked no questions as to the symptoms, prognosis, differential diagnosis, or treatment; and he moved, "That attention is specially desired to the defects in the anatomical and physiological parts of the examination, and also to important deficiencies in the clinical examination."

Dr. Rolleston seconded the motion.

Dr. Quain opposed the motion, believing that it would be sufficient to send down the reports to the bodies without special comment.

Mr. Macnamara had no doubt that due attention would be paid to the recommendations of the visitors; if not, he should be prepared to support Sir W. Gull's motion. If the wishes of the Council were not complied with, the Apothecaries' Hall could be reported to the Privy Council.

Dr. Rolleston said if the reports were to be sent down to the bodies without comment, they might as well be sent *en masse*, and the Council was only wasting its time in discussing them.

Sir W. Gull said that the clinical examinations of the Apothecaries' Hall were a mere sham, and he was surprised that any hesitation should be felt about calling special attention to their deficiencies.

After some further discussion Sir Wm. Gull's motion was put and negatived, 9 voting for it and 13 against.

Dr. Rolleston then brought forward a motion to rescind the resolution that the reports of the visitors be considered *seriatim*; but, after a short conversation, the motion was withdrawn.

Dr. Humphry moved,—"That the visitations of examinations be continued, so as to effect the visitations of the examinations, in part or in whole, of two or three of the licensing bodies in each year; and that it be referred to the Executive Committee to consider in what manner this may best be done, and to report to the next meeting of the Council." The Council, he said, had done a good and a great work by means of the visitations. All the bodies had been reported upon, and the public and the profession could now form an opinion as to the manner in which the work had been carried out. A large number of the bodies had modified their examinations; others contemplated doing the same, and in all probability all the examinations throughout the country would be more or less improved. The work, though an expensive one, had been carried out with great economy of time and money, notwithstanding the number of examinations visited. This was due to the admirable arrangements of the Executive Committee, to the hearty assistance of the visitors who were not members of the Council, and to the cordial co-operation of the licensing bodies themselves. He had had at first some apprehensions in taking part in the labour of visiting; but as soon as he entered upon the work all his apprehensions ceased. These examinations should be limited to two or three bodies in the year, which would be sufficient to keep up the interest of the work.

Mr. Macnamara seconded the motion, and said he thought the work of visitation had been the most important of any undertaken by the Council. If it were continued, he thought we should soon arrive at a high standard of medical education.

Dr. Sharpey supported the motion, and suggested that the bodies not visited in any year should be requested to make returns as to certain particulars of their examinations for the information of the Council.

Dr. Wood thought that there ought to be a Sabbatical year in regard to the visitations. The bodies were doing their best to comply with the wishes of the Council, but that they ought not to be pushed on too fast. On the score of economy also, it would be well to defer the visitations, the Council having during the past year exceeded its income by £1000.

Dr. Bennett also thought that there should be a respite, so as to give an opportunity to the bodies to effect the desired improvements.

Dr. Quain expressed a similar opinion.

Mr. Quain suggested that the various schools should be visited. At present, he said, there were no opportunities of ascertaining whether the students had ample means of education.

The motion was then put and carried.

On the motion of Dr. Sharpey, seconded by Dr. Rolleston, the following motion was agreed to:—"That the following be referred to the Executive Committee for their consideration and report: That, in the case of examinations not visited in any given year, the respective licensing bodies be requested to furnish the Council with returns to the following effect:—(*a*) The names of the examiners. (*b*) Copies of the written or printed questions; the time allowed for answering them; and the judgment passed on the answers. (*c*) The time devoted to the oral and practical examinations; the plan followed in conducting them; the nature of the specimens, preparations and other appliances made use of; and the practical exercises the candidates were called on to perform. (*d*) An account of any changes introduced since the date of the last information received by the Council."

On the motion of Mr. Macnamara, seconded by Dr. Pyle, it was resolved, "That the following motion be referred to the Executive Committee for their consideration and re-

Statement of the Degrees, Diplomas, and Licences of the Candidates for Commissions in the Medical Department of the Army, who, on the 10*th August*, 1874, *presented themselves for Examination, showing the number that passed, and did not pass, distinguishing the Qualifications, both Medical and Surgical, under the several Licensing Bodies.*

port:—That it be a direction to the Executive Committee, in their future selection of visitors of examinations, so far as practicable to arrange it so that visitors shall not be called upon to report upon examinations held in that division of the kingdom in which the visitors themselves may be resident.

The Council then adjourned.

Tuesday, June 22nd.

ARMY RETURNS.

The returns from the Army Medical Department (see page 13) were laid before the Council.

The returns were ordered to be inserted on the Minutes, and thanks were voted to the Director-General.

EXAMINATIONS IN ANATOMY.

Mr. Macnamara moved—"That, in the opinion of this Council, all examinations on anatomy should, as far as practicable, include the performance by each candidate of actual dissections, and that all those on surgery should include the performance by each candidate of two or more operations on the dead subject." It was more important, he said, for the student to be properly grounded in anatomy than in any other branch of medical science. Other subjects could be worked up afterwards, but this could not. The subject of anatomy was now enforced by the Royal College of Surgeons in Ireland; and he was informed by a gentleman very largely engaged in teaching that the attendance in the dissecting-rooms had been greatly increased in consequence. As to the practicability of his proposal, he was informed that at the Queen's University as many as 120 candidates had been examined in actual dissections at one examination; and the same system was adopted with success at Trinity College and at the Royal College of Surgeons in Ireland. The fact that a candidate would be liable to be called upon to dissect and operate would lead him to take up the subject at an early period of his career.

Dr. Pyle seconded the motion.

Dr. Rolleston said the members were all at one as to the importance of practical dissections; the only difference between them was as to the methods of securing it. He would propose as an amendment—"That it is desirable candidates in examinations in anatomy should understand that they may be called upon to perform actual dissections, and that candidates in examinations in surgery should understand that they may be called upon to perform one or more operations on the dead subject." The words "as far as practicable," in Mr. Macnamara's motion, were, in his opinion, somewhat too elastic. Every candidate should be obliged to go through a certain amount of constructive, synthetical, and microscopic examination. He thought that a candidate who could write a good paper, recognise dissections shown to him, and prepare microscopical preparations, might be regarded as competent.

The amendment of Dr. Rolleston was then put and carried.

THE COUNCIL AND THE LICENSING BODIES.

Dr. Parkes proposed—"That the Registrar be directed to write to the several licensing bodies, and to inquire what steps have been taken to carry out the 17th, 18th, and 21st Recommendations of the Council in Section v., page 17 (Professional Examination) of the 'Recommendations and Opinions of the General Medical Council, 1874.'"

The Recommendations referred to are as follows:

"17. That the Council recommend that, in the case of certificates presented before admission to the examinations of the several licensing bodies, each should include a statement from the teacher or teachers that the candidate had satisfactorily attended examinations, from time to time, held on the subject of study to which the certificate relates. (Minutes of General Council, July 15, 1874, p. 51.)"

"18. That it is desirable that, in the examinations on several of the subjects of the curriculum—such, for example, as botany, zoology, chemistry, and materia medica—the area of examination should be limited and defined. (Minutes of General Council, July 15, 1874, p. 51.)"

"21. That it is desirable that observation with the microscope should form part of the examinations of candidates for a licence. (Minutes of General Council, July 16, 1874, p. 60.)"

Dr. Apjohn seconded the motion.

Sir D. Corrigan referred to the difficulty of carrying out the recommendations in question.

Mr. Turner thought that the recommendations should be forwarded to the teachers of schools.

The President thought that the subject would be a fit one for the consideration of the Executive Committee, whose attention, he believed, had already been called to it. He thought that the matter should be left with the Executive Committee with the full understanding that they should make the recommendations public in the way they thought best.

Dr. Sharpey said there was no provision in the Medical Act for any official communication between the Council and the schools; all such communication should take place with the licensing bodies.

Dr. Thompson said there need be no difficulty in the matter, because if the licensing bodies chose to act in accordance with the recommendations, they had simply to give it out that their examinations would be shaped accordingly, and all teachers would be then aware of the fact.

Dr. Wood doubted whether the licensing bodies had been paying attention to the recommendations. If they were sent down as proposed the bodies must take cognisance of them.

Dr. Bennett saw no objection to the motion of Dr. Parkes, but he thought that attention had really been paid to the Council's recommendations by most of the licensing bodies. The proper course would be to communicate with those bodies, who would give effect to the recommendations in their requirements.

Mr. Macnamara said that the College of Surgeons in Ireland had, in deference to the wishes of the Council, introduced the microscope at its examinations.

Mr. Quain alluded to the importance of class examinations.

Dr. Rolleston referred to the difficulties experienced in reference to recommendation No. 17, and proposed, "That in Dr. Parkes's motion the word '17th' be omitted, and the words '19th, 20th,' be introduced after the word '18th.'" No. 19 required the presence of two examiners, and No. 20 stated that in no case should an examination be conducted wholly or in great part by the lecturer or teacher.

Dr. A. Smith seconded the amendment.

Dr. Parkes said he had not included Nos. 19 and 20 because they had been already referred to in the answers of the licensing bodies.

Dr. Rolleston said he objected to No. 17 on the ground that the judgment of the examiners should be founded entirely upon the actual examination independently of any certificate of teachers, which might open the door to corruption. If a candidate showed that he possessed adequate knowledge, it was really of no consequence how he came by it. They had no right to interfere directly with the methods of teaching, but only indirectly by means of examination. With these they were potent to deal, but they need not inquire as to the mode in which knowledge was communicated. He was in favour of teachers having a share in the examinations, but not of their keeping it all in their own hands, and he considered that one examiner should have the power of plucking.

Dr. Parkes said he would consent to include Nos. 19 and 20 in his motion if Dr. Rolleston would allow him to retain No. 17.

Dr. Rolleston declined to accede to this suggestion.

Sir W. Gull thought that recommendation No. 17 involved a dangerous principle. Examiners should rely upon their own examinations exclusively, and he would vote against any rule giving weight to the certificates of teachers.

Dr. Storrar, alluding to recommendation No. 18, protested against the excessive legislation in such matters, which, he said, should be left to the common sense of examining bodies.

Dr. Wood said if Dr. Storrar was more acquainted with the machinery of examinations, he would know that there was a *raison d'être* for the regulation in question. The students were greatly overloaded with subjects for examination, and unless their areas were somewhat limited it was impossible to have a satisfactory examination. By such a limitation the candidates could be examined more stringently than if the whole area were left open. He protested against getting rid of the recommendation by the side wind of refusing to send it down to the licensing bodies. It was appalling to think of the number of rejections at some of the examinations, but he believed that if the recommendations of the Council were duly carried out, the evil would no longer exist. The same discredit did not now attach to being plucked as formerly. A plucked man used to be reckoned a pariah, but now a student did not care a fig about it.

Dr. HUMPHRY said that Dr. Wood had given the real reason for the adoption of recommendation No. 17. He believed that too much stress was sometimes laid on the final examination. Whatever the final examination was, there would be a system of cramming men for it in a short space of time. The great desideratum was, not the final examination, but good teaching. Where there was good teaching there would be good men, and the great element in good teaching was repeated examinations during the course of instruction. He therefore supported the retention of recommendation No. 17.

Dr. QUAIN said that the recommendations had been deliberately adopted by the Council, and he thought that a discussion as to their propriety was now out of place.

Dr. APJOHN said that at Trinity College periodical examinations were held by the professors with great advantage. With regard to the limiting the area of certain subjects referred to, he feared that it would favour mediocrity and discourage high attainments.

Dr. THOMPSON thought that by sending down the recommendations in question, the Council would be diminishing the weight of other recommendations as to which no such inquiry was made.

Dr. SHARPEY thought that the transmission of the recommendations would be the means of eliciting some useful information from the licensing bodies.

Sir D. CORRIGAN suggested that all the recommendations should be sent down, instead of selecting three or four. The propriety of the recommendations ought not now to be discussed, the Council having deliberately adopted them; nor could the Council now reopen the question as to the relative merits of education and examination. He concurred with Sir W. Gull on that point, and dissented from the views of Dr. Humphry. All they had to do was to ascertain whether the candidates possessed the required knowledge.

Dr. PARKES expressed his willingness to adopt Sir D. Corrigan's suggestion.

Sir W. GULL thought the best form of resolution would be to instruct the registrar to write to the licensing bodies to inquire whether they had any observations to offer to the Council on the recommendations of 1874 respecting the professional examination; and also to inquire how far they had been enabled to carry such recommendations into effect.

Mr. TURNER expressed his concurrence in that view.

The other proposals were then withdrawn in favour of Sir W. Gull's, which was unanimously adopted.

A COMPLAINT.

A statement was read from Mr. R. Vandaleur Kelly, licentiate of the College of Physicians and the College of Surgeons, Edinburgh, complaining of the conduct of the President of the College of Surgeons in Ireland, in permitting Dr. G. Stokes, a fellow of that College (who, together with himself was a candidate for certain medical appointments in Ireland) to take a copy, which was certified by the President, of a record of the College showing that he (Mr. Kelly) had been rejected at an examination instituted by that body, which record was made use of to his disadvantage by his rival candidate. The statement was accompanied by a lengthened correspondence between Mr. Kelly and the College of Surgeons, Ireland, which was also read.

Mr. MACNAMARA explained, in answer to Dr. Wood, that Mr. Kelly asked for an examination of the College of Surgeons, because the licence of that body was necessary in order to enable him to fill the office for which he was a candidate.

On the motion of Sir W. GULL, seconded by Dr. QUAIN, the Council resolved that the case of Mr. Kelly was not one for their consideration.

STATE MEDICINE.

The following letter was read from the representative in the Medical Council of the University of Oxford, respecting examination in State Medicine, referred by the Executive Committee to the General Council:—

Anatomical Department, Museum, Oxford,
February 9th, 1875.

SIR,—I have been requested, as the representative of the University in the Medical Council, to lay the following resolutions before the Medical Council:—

Extract from Report of Committee on Medical Education of the Hebdomadal Council of the University of Oxford.

"That it is expedient to provide, or to assist in providing, an examination in the subject called State Medicine or sanitary science."

"That it is thought best that such a qualification should not be granted severally by different licensing bodies, but, like the qualification for general practice, should depend on an examination authorised by all, or as many as possible, of the licensing bodies acting conjointly."

Resolution of the Hebdomadal Council thereupon.

"That the medical representatives of the University be authorised to inform the Medical Committee of Reference, and the Medical Council, that the Council has adopted the recommendations of the Committee, and is prepared to recommend corresponding action to the University when the proper time arrives."

I am, Sir, yours faithfully,
GEORGE ROLLESTON,
Representative of the University of Oxford
in the Medical Council.

To the President
of the Medical Council.

Mr. TURNER would be glad of a little more information as to the proposed examination and degree, and what the University of Oxford had done in the matter.

Dr. STORRAR deprecated raising the question of State medicine with reference to the University of Oxford only; other bodies having taken action in the matter.

Sir D. CORRIGAN objected to letters being received from a member of the Council (Dr. Rolleston), who, being present, could make any verbal statement that he might desire.

Dr. QUAIN said that Dr. Rolleston's letter enclosed the resolution of an important body, which was very properly brought before the attention of the Council.

Dr. PARKES said the subject was one of great importance, and he thought the Council ought to express approval of any effort in the direction indicated.

It was resolved that the letter of Dr. Rolleston be entered on the Minutes.

MISS GREENSTREET'S CASE.

A letter from Mr. Ouvry was read expressing an opinion that Miss Greenstreet, whose case was mentioned at a previous meeting of the Council, was not entitled to register the licence in midwifery which she had obtained from the King and Queen's College in Ireland.

On the motion of Dr. Smith, seconded by Dr. Thomson, the Council, acting on the advice of its solicitor, declined to register Miss Greenstreet's qualification.

FINANCE.

The following Report of the Finance Committee was read and received:—

"The Finance Committee report that the income of the Council during the year 1874 has been £6004 6*s.* 2*d.*, a sum which exceeded the income of the year 1873 by £666 5*s.* 7*d.* The expenditure of the Council during the same period has been £6882 16*s.* 9*d.*, a sum which exceeded the expenditure of 1873 by £1757 13*s.* 8*d.* It appears that the expenditure of the year 1874 has exceeded the income of the year by the sum of £878 10*s.* 7*d.*, and that the increase of expenditure during the year in certain items is £1336 1*s.* 2*d.* Of this sum £688 18*s.* 6*d.* has been spent in reprinting the Pharmacopœia and Additions, an outlay which is in course of reimbursement. A second large item of expenditure is for house expenses, incident to coming into possession of the new premises. On the other hand, a decrease in certain items of expenditure to the amount of £262 7*s.* is shown, leaving a net increase of expenditure by the General Council during the year 1874, as compared with 1873, of £1073 14*s.* 2*d.*

"In former reports approximate estimates of the income and expenditure for the year ensuing were given. Little advantage has resulted from this practice, and, as much uncertainty must for the present exist as to the expenditure in connexion with the new offices and premises, it has been thought undesirable to present an estimate for the next year.

"The Committee report that, in accordance with the resolution of the Executive Committee (Jan. 21st, 1875), the accounts of the General Council were submitted for audit to Messrs. Quilter and Ball, professional auditors, and were found correct.

"Richard Quain, M.D.,
"June 21st, 1875." Chairman.

REPEAL OF THE 46TH SECTION OF MEDICAL ACT.

A report was read from the Committee appointed to consider the proposed repeals of parts of the Medical Acts, submitted to the consideration of the Council by Mr. Rickards, the Speaker's counsel.

Some discussion took place as to the privileges conferred by clause 46, and several members expressed an opinion that it would not be desirable to relinquish them. Ultimately the consideration of the subject was withdrawn.

It was moved by Mr. Turner, seconded by Dr. A. Smith, and agreed to, "That it be referred to the Executive Committee to employ an expert for the preparation of a general index of the first ten volumes of the Minutes of the General Medical Council, to be printed before the meetings of Council in 1876."

The Council then adjourned.

Wednesday, June 23rd.

The Council again went into committee on the reports of the visitations of the examinations, and proceeded to consider that of Trinity College, Dublin.

Dr. Apjohn referred at some length to the report, and gave explanations as to the remarks of the visitors, which, however, were for the most part inaudible.

Dr. Stokes expressed the pleasure which he had derived from the perusal of the report of the visitors. Referring to the suggestion of the visitors that the time devoted to the *vivâ voce* clinical examination was too short, he expressed his belief that a judgment as to the *mens medica* of the candidate could be better arrived at by a written description of a case than by answers to any number of oral questions. Remarking on the proposed exclusion of the professorial element from examining boards, he said it implied a want of confidence in the morality of the examiners.

Dr. Storrar doubted the expediency of allowing a candidate to come up at different times for different parts of his examination, which rather favoured a superficial knowledge that could easily be obtained by cramming.

Dr. Haldane, one of the visitors, said he was greatly pleased with the oral clinical examination, but the time was no doubt rather too short.

Dr. A. Smith thought that the time of examination was sufficient, and said that the best papers were often written in the shortest time.

Sir D. Corrigan said if the visitations were continued it would be necessary to instruct the visitors as to the special matters to be inquired into. On examining the reports he found in them no identity of purpose and no similarity of information. He then called attention to the regulation of Trinity College permitting any person to attend the medical lectures on the payment of a fee of 5*s*. This was a regulation to which he thought the visitors ought to have called attention. They ought also to have noticed the fact that a student was permitted to take a licence in medicine after four years' study in medicine and two years' study in arts; and that on completing his arts course, and taking a degree of M.B., he was not subjected to a further examination in medicine.

Mr. Quain said he believed that in other universities a man might take a medical degree without any degree in arts at all; so that there was no special transgression on the part of Trinity College.

Dr. Storrar stated that at the University of London the student was not compelled to take a B.A. degree before taking the degree in medicine.

Dr. Humphry said it was the same at Cambridge, but the candidates had to go through a very similar examination to that required for the arts degree.

Dr. Rolleston said that at Oxford the medical candidates were required to go through the arts curriculum and also to take the degree. He urged the Council to take into consideration the question of permitting different parts of examinations to be taken at different times—a practice that favoured the grinding system, and often led the examiners to intensify their questions to such an extent as to make them beyond the capacity of average students.

Mr. Macnamara said at Trinity College the examination of the licentiate was exactly the same as that for the degree of M.B.

Sir D. Corrigan repeated that there was no special examination for a degree of M.B., but that the degree could be taken by completing the arts course and paying the requisite fees.

Sir W. Gull said that the examination for the licence was also an examination for the degree of M.B. The only difference between them was that one person had a longer university career than the other.

The report of the visitors was then ordered to be sent to Trinity College for consideration and remarks.

The report of the visitors of the examinations of the Durham University was then considered.

Dr. Pyle made some comments on the report, and, alluding to the remark that the examination was conducted exclusively by the teachers of the University, said that was an accidental circumstance, and not in accordance with the system usually adopted. In the arts course the University had for the last thirty years had one or two examiners from Oxford, so that he could hardly understand how it was that a candidate at the examination (a graduate of the University) should show such deficiencies as were alluded to in the composition of his thesis.

Dr. Wood thought it very remarkable that a university should confer the degree of M.A. upon a man who was ignorant of composition and spelling. Such an occurrence was neither creditable to the University nor to the profession. It was thought that no responsibility in regard to such matters rested with the medical examiners; but he maintained that they ought to reject any candidate who showed a want of general education. No illiterate man should ever be allowed to enter the profession. When such candidates, who had obtained arts degrees, appeared at professional examinations, he thought that the examiners should take special notice of the circumstance, ascertain who were the examiners in general education, and report to the Council in order that the matter might be remedied.

Mr. Turner called attention to the fact that a candidate was allowed to present himself a second time for practical chemistry on the ground of his papers in anatomy and physiology being considered good, and his paper work in chemistry fair. This candidate, however, was said to have made a very indifferent dissection. Under the circumstances, he thought that the candidate should not have been allowed a second chance. He also maintained that no thesis should be accepted unless it was creditable in a literary as well as in a scientific point of view. He demurred to a remark made by Sir D. Corrigan, that the writing of a thesis was a sham. At Edinburgh they required the candidate to certify that his thesis was of his own composition, relying upon his honour for the correctness of the statement. The thesis was required to be a good literary composition, and to contain the results of the writer's own inquiries and observations.

Dr. Storrar said that the University of Durham had the merit of having introduced the system of practical examinations at a very early period. What they really wanted was to have outside examiners. It was creditable to the University that it had resisted the temptation of granting in the north of England the old-fashioned St. Andrews degrees.

Dr. Humphry said that importance of dissections was shown by the circumstance mentioned in the report that the candidate who had made such a "hash" of his dissection had obtained 93 marks out of 100 for his paper on anatomy.

The President said that when he visited the University fifteen years ago a similar circumstance occurred to that mentioned by the visitors with regard to the examination in arts, and he then used almost the same words as the visitors had done—viz., that it was hard upon the professional examiners that they should be placed in the dilemma of passing persons who could not write or spell English, and who ought never to have had an arts degree. It was in consequence of the indelible impression then made upon his mind that he was led in his address to remark upon the condition of the arts examinations. Sooner or later it would be the duty of the Council to consider whether those examinations were what they had a right to require.

The Council then adjourned for an hour, to give an opportunity to several of the Committees to continue or complete their labours.

At the reassembling of the Council

Dr. Wood moved the adoption of the resolutions of the Committee of the Council with reference to the reports of the visitors.

Sir W. Gull seconded the motion.

Dr. Thomson moved as an amendment that the resolutions be adopted, with the exception of that passed with reference to the Royal College of Physicians. That body, he said, was the only one whose attention was especially called to deficiencies in the examinations, although there were other bodies whose examinations were shown to be defective. The proceeding was, he thought, a partial one. He believed that it would have been better to send down the reports without comment. They had not yet been considered by the bodies themselves, and special allusions were therefore at present inexpedient. At any rate, it was undesirable to single out one body for remark.

Mr. Quain seconded the amendment.

Sir W. Gull thought that the amendment would but confirm the Council in a vicious mode of proceeding. It was not enough, he thought, to send down the reports of the visitors; and he deprecated the waiting policy so often advocated by members of the Council.

Mr. Quain complained that Sir W. Gull, in reference to this matter, had not been so courteous as he might have been to the other members of the Council.

Sir D. Corrigan could not admit the argument, that because the Council had failed to censure other bodies, therefore no remark should be made with reference to the College of Physicians. To be consistent, however, the better course would be to introduce all the other bodies into the resolution, so as to deal with all alike.

The amendment was then put and negatived, 8 voting for it, and 10 against. The motion was put and carried.

Dr. Storrar gave notice that he would move at the proper time: "That the duties to which the General Medical Council are appointed are defined by the Medical Acts, and the Council are of opinion that their appointments do not authorise them to represent to the Government the views of the profession on the large social question of the expediency or otherwise of admitting women to practise medicine."

Letters were then read from Miss Jex Blake and Mr. Arthur Norton with reference to the registration of women; and also a letter from Dr. Shuttleworth on the subject of Mr. Cowper Temple's Bill. These letters were ordered to be entered on the programme.

The Council then adjourned.

Thursday, June 24th.

REGISTRATION OF WOMEN.

The Council took into consideration the letter addressed to the President from the Medical Department of the Privy Council, and which will be found in our last number, p. 891.

The President asked the opinion of the Council as to what course should be pursued. The Chairman of the Committee proposed to move the reception of his report; but they must decide in what way they would deal with the notices of motion which followed on the programme—namely, those of Sir Dominic Corrigan, Dr. Andrew Wood, and Dr. Storrar. There was also a notice of motion given by Dr. Bennett, which was in the printer's hands. This motion, like the motions of Sir Dominic Corrigan and Dr. Wood, was an alternative report, so that there were, in fact, three alternative reports claiming the attention of the Council. The motion of Dr. Storrar stood in a somewhat different category; it was not an alternative report, but it was definitely an amendment. Unless there was an objection to such a course, he would call at once upon the chairman of the committee to move the reception of his report.

Dr. Storrar wished it to be understood that he should have the privilege of bringing forward his amendment before the report of the committee was considered.

Sir D. Corrigan objected to that course, his own amendment coming before that of Dr. Storrar on the programme.

The President said the fairest course would be that all three of the alternative reports should be treated in the same way as the original report, as regards being received and entered on the Minutes, as sooner or later they must be.

After some further discussion as to the order in which the various proposals should be discussed, the President called upon Mr. Turner to move the reception of his report.

Mr. Turner.—The Council will observe that this motion is purely a formal one, that the report be received and entered on the Minutes; but at your suggestion, Sir, I think this may be the right stage for me, acting as chairman of the committee, to explain the report which we have handed in. Going, then, to the proceedings which have taken place during the last few days, I may say that the committee have arrived at the conclusions stated in that report with a due sense of the responsibility of the task imposed upon them by the Council, and that the conclusions arrived at have not been arrived at hastily. We have had four meetings, and we have spent several hours in the discussion of the various points raised. All the members of the Council, I have no doubt, have read Mr. Simon's letter written by direction of the Lord President; and all are aware that there are two important questions raised in that letter, the first with reference to the Bill introduced by Mr. Cowper-Temple to amend the Medical Act of 1858, so far as relates to the registration of women who have taken the Degree of Doctor of Medicine in a foreign university, and the opinion of the Medical Council is requested on the subject. We are asked also to favour the Lord President with our observations upon it. Now, I think, Sir, there can be no doubt at all that the consideration of this Bill falls within the legitimate province of this Council. We are a Council of Medical Education and Registration. The registration of foreign degrees is specially referred to in one of the clauses of the Act under which we are constituted, so that clearly any emendation of that Act or that clause comes naturally before us. The committee, therefore, had no difficulty in taking into consideration this part of Mr. Simon's letter, and I think I am right in saying that the committee came to a unanimous conclusion as to the kind of answer which should be given to the Lord President on this matter. The answer of the committee will be found on page 7 of the programme of business of this day, and I may as well read the terms of the answer which we apprehend should be sent to the Lord President. "In regard to Mr. Cowper-Temple's Bill, the Council cannot approve of a measure intended to confer on women the privilege of registering certain foreign degrees from which, under clause 46 of the Medical Act, men are debarred, and over the education and examination for which the Medical Council have no means of exercising that supervision and control to which all licensing bodies of this country, whether universities or medical corporations, are subjected." The Council are asked to express an opinion with regard, on the one hand, "to women who desire to obtain legal status as medical practitioners in this country"—(I am quoting from Mr. Simon's letter)—"and, on the other hand, to the examination rules or other conditions which prevent them from accomplishing their wish. His Grace would be glad that the observations with which the Medical Council may favour him should not be restricted to the particular proposal of Mr. Cowper-Temple's Bill, but should discuss, as fully as the Medical Council may see fit, the object to which that proposal would contribute." With reference, then, to the more general question raised in this part of Mr. Simon's letter, there is naturally room for a much greater difference of opinion than was found in connexion with the first point—namely, Mr. Cowper-Temple's Bill. The opinion was expressed at the committee, and I should observe that it is the opinion also of another member of the Council not a member of the committee, and he has expressed this opinion in the form of the motion on page 14—I refer to Dr. Storrar's motion,—that this was a subject which did not legitimately fall within the province of the Medical Council—that we are a Council of Medical Education and Registration, and we have nothing whatever to do with the consideration of so wide and general a question as that which has been brought before us. Now, I have no doubt that Dr. Storrar is technically correct in the view which he has taken up, and which he has embodied in his motion; but the question that the committee had to consider was, whether we should avoid by a mere technicality the expression of our opinion; whether, when the question is directly submitted to us by an important department of the Government, we should not express some opinion on that question; whether, for example, it would not be a breach of courtesy on our part if we declined to enter into the consideration of this matter which has been submitted to us. And I may mention that I have heard complaints expressed that the Government did not sufficiently consult the Medical Council on various questions connected with the medical profession on which this Council might fairly be asked to express an opinion. Certainly, if we were to refuse to enter into this matter, it is not likely that we should ever be again appealed to by the Government. On this ground, therefore, if on no other, I think it very important that we should, as far as we can, endeavour to give some opinion, whether it be favourable or not, as to the question which has been submitted by the Lord President. The committee, then, taking this view of the case, considered that we were bound to say something on the general question. But, Sir, another preliminary question was raised in the committee before we felt ourselves prepared to go into the consideration of the general matter, and this question has been embodied in a motion, notice of which has been given by Sir Dominic Corrigan, and which you will find expressed at page 10 of our programme to-day. Sir Dominic's idea is this—and he submitted it to the committee for consideration,—"that the members of the Council do not feel authorised in expressing a decided opinion without first submitting the matter to the consideration of the several licensing bodies whose representatives they are; and, if it seem fit, to the Lord President, that the members of the Medical Council should obtain the views of the licensing bodies whom they represent, they will, as soon as possible, obtain the information for the Lord President." The committee considered this proposition, and they decided that if they adopted this proposal of Sir D. Corrigan it would be, practically, shelving the question for an entire year. The Government do not ask for the opinion of the various licensing bodies, but they ask for the opinion of this Council; and, therefore, we ought not to hesitate to express our opinions in the matter. We, therefore, decided on the following paragraphs in our report, which paragraphs, with your permission, I shall read. "The committee, having taken this letter into consideration, recommend the General Medical Council to adopt the following as the reply to be sent to the Lord President of the Privy Council:—In reply to the communication addressed to them by the Lord President of the Privy Council, the Medical Council have to state that, being thus directly appealed to by the Lord President, they have felt bound to consider the question of the admission of women to the medical profession." Then, having decided that we should take up this question, the next point for our consideration was what answer we should give, and this was a much more intricate matter,—what answer should be given to the question propounded by Mr. Simon's letter—whether women ought to be able to look to medical practice, or certain branches of it, as open to them equally with men as a profession and means of livelihood. This naturally excited very considerable discussion in the committee; but, after framing several paragraphs in reply, and after much consideration, we at last decided upon recommending the two following paragraphs, which I shall, with your permission, Sir, now read. "After due deliberation, the Medical Council have to express their opinion that the study and practice of medicine and surgery, instead of offering a field of exertion well fitted for women, do, on the contrary, present special difficulties which cannot be safely ignored, and some of which cannot be obviated. Instead of medicine offering more facilities and less difficulties for women than other professions, the Medical Council believe that, as the whole question is looked into, there will be found peculiar hindrances, moral and physical, to the successful pursuit of medicine by women. Moreover, they desire to add that if it be admitted that women should enter the medical profession, the existence of an equal fitness for other professions must be assumed." Now, Sir, perhaps it may not be considered out of place if I should give one or two reasons why I agree to the statements made in these two paragraphs and in giving these reasons I do not wish to commit any other member of the committee to the reasons which I may advance. These are my own personal and individual reasons. Doubtless other members of the committee will be quite prepared to state why they agree to the admission of paragraphs expressing these very decided sentiments. In giving my reasons I can assure you that there is no wish on my part to say anything that might hurt the feelings of anyone, either man or woman, in this matter. It would ill become me, who throughout all my life have had domestic relations with the opposite sex which are all that could be desired, to say one word which might be regarded as depreciating the sex which we all value and esteem so highly. Still, however, there are certain general facts which I think ought not to be ignored in discussing this question, and facts which, I am sorry to say, have been too much ignored in looking at the important bearings of this question. I have heard it argued that men and women are alike in capacity, that what is open to the man to do ought to be open to the woman to do; that woman has no distinctive sphere. I have heard that point broadly stated, and I have heard great ridicule thrown upon those who have asserted that woman has a distinctive sphere. Now, Sir, to my mind all such statements as these are mere idle talk. No amount of special pleading or ingenious argument can break down the physiological barrier which separates the two sexes from each other. Woman is not man any more than man is woman. The sexes are not on a footing of equality. They ought not to be rival claimants for the same object. Each has its own excellence, and one is the complement of the other. I believe, Sir, that it is a perfectly sound physiological doctrine when I state that the physical framework of a woman is inferior in its capacity and power to the physical framework of a man. Her muscular apparatus is less powerful, her bones are more slender, her skull is smaller, and, if I may say so, exhibits a smaller amount of departure from the infantile condition than is to be found in a man. Her brain, also, is smaller and lighter. Now, clearly, Sir, these important anatomical differences find some physiological expression. The difference between the weight of the brain in a man and in a woman respectively is, on an average — and I am referring only to averages because there are exceptions, of course, in both cases —the difference between the weight of the brain in a man and in a woman is as much as 10 per cent., and that difference is in favour of the male. Now this, I think, is a fact of great physiological significance. If we regard, as we all do, the brain as the centre of the intellectual faculties, and as the centre of the sensori-motor activity, it is clear, I think, that this lower brain-weight implies a smaller capacity for concentration of thought, for intellectual activity, and for prolonged exertion, either mental or bodily. But, Sir, it is not merely in connexion with the physical attributes that the two sexes differ. In woman the emotional qualities greatly preponderate over the logical. Now this is one of the most valuable characteristics of women—the preponderance of the emotional qualities. It gives them all those characteristics which we value so much in a wife and mother, and which are also of the greatest importance in connexion with the functions of a nurse which she is so often called upon to perform. These qualities, therefore, are those which make her truly a helpmeet for the man. But the preponderance of the emotional qualities in woman's nature, I submit, ill adapts her for the performance of those duties which are entailed upon those who enter the profession of medicine. In the profession of medicine, what is so much desired is the clear exercise of the logical faculty. If medicine is to be advanced as a science, it can only be by the application of scientific principles to the study of disease. Now, Sir, while the pages of history bristle with the names of men who have added to our scientific knowledge, I am not aware that the name of a woman occurs in connexion with the discovery of any leading scientific fact, or scientific theory. Hence, I think, Sir, that the whole history of our race shows that in this matter of the possession of logical and scientific faculty, women have not yet shown that they possess any power of coming to the front. I put forward these considerations as arguments in support of one of the statements contained in one paragraph that I have read—that there are peculiar hindrances, moral and physical, to the successful pursuit of medicine by women. Sir, it may be said that all men do not possess the logical faculty. It may be said that there are many members of the medical profession who have not this faculty, who have not the power of eliminating, in the consideration of a case, all sources of error, and of limiting themselves merely to the consideration of those facts which are based upon a correct consideration of the case in question. Undoubtedly this is true. But I doubt very much whether the introduction of a new element into our profession—an element as to which, I think, experience has shown us that the logical or scientific faculty has not yet exhibited itself—I doubt very much whether this would tend to improve the standard of medical practice in this country. I would especially direct attention to that part of the paragraph on page 5 which reads thus:—"Moreover, they desire to add that if it be permitted that women should enter the medical profession, the existence of an equal fitness in women for other professions must be assumed." This, also, was carefully considered by the committee before it was introduced into our report; and I think I may say that it was felt that the medical profession had been made a sort of battle-field upon which was to be fought out this question which has come so prominently forward of late years, as to the equality of the two sexes; and many of us felt that it was not right or fair to our profession that it should be made the battle-ground on which this great question was to be fought out. Those, then, were my reasons for agreeing to the introduction of the two paragraphs which I have referred to. It will be seen, therefore, that we had many weighty objections to bring to the consideration of the Lord President against the introduction of women into the medical profession. Still, we felt that if the Government and the Legislature should in their wisdom see fit to give facilities and offer encouragement for the introduction of women to the profession of medicine, it would be seemly for us to indicate how this might be done, and to lay down certain propositions or conditions that we thought ought to be carried out, if possible, in connexion with this matter. Accordingly, you will find on pages 5 and 6 certain recommendations of the committee. The first of these recommendations is to the effect "that in the interests of public order the education and examination of female students of medicine should be conducted entirely apart from those of males." Now, Sir, I do not think that I need dilate upon this matter. All of us who are sitting round this board know exactly what a medical education is. We know what medical students have to go through in their endeavours to obtain such an education, and we know that circumstances are constantly arising which render anything like a mixture of the two sexes extremely improper; so that I do not apprehend that there should be any difficulty at all in the Council agreeing to a condition of this kind. Then in the second paragraph we say: "With regard to the examination rules or other conditions which prevent women from obtaining a legal status as medical practitioners in this country, it would be sufficient if an Act of Parliament were passed which should enable the Medical Council to recognise the examinations of the licensing bodies under Schedule A of the Medical Act, separately or conjointly, or such other examination or examinations as the Medical Council may, from time to time, deem sufficient for the purpose of granting admission of women to the Medical Register under the title of 'licensed practitioners of medicine.'" Well, now, we had considerable difficulty indeed in coming to the conclusion as to how women should be admitted to the Medical Register. That was obviously a matter of great difficulty, and also one of great importance, whether women should be allowed to present themselves for the usual examinations for licences and memberships and degrees of universities and so on, or whether there should be some special licence created for the purpose of granting admission to the Register. You will observe that we have recommended that a special licence should be created for their special behoof. It seemed to us that if they were allowed to obtain the ordinary licences and degrees, not only should we be giving them power to be inserted in the Register, but we should also be giving them certain rights and powers in connexion with the corporations or universities from which these degrees were obtained. Now it seemed to us that we had no right to recommend any such course to the Medical Council, but that that was a matter that went beyond the remit that had been made to us, and we thought that the proposal we have made was the best mode of meeting the difficulty. Then there is the paragraph numbered 3:—"That examinations of female candidates for a licence entitling their names to be placed on the Register should be of the same character as those of males." As to the inclusion of this clause there was some difference of opinion. One member, if not more, of the committee thought that there was no need for it; but it was felt by the majority that it was advisable to put forward a public declaration of this kind so that it might be seen that we did not wish imperfectly educated persons to be put on the Register—that is to say, persons who had received a lower standard of education than the men. We considered that the standard of education for the two sexes should be the same. Then we have the fourth paragraph—"That the education and examinations for these licences should be under the supervision of the Medical Council in the same way as is required for the other licences of this country." We were all agreed as to that. I do not think that there was any difference of opinion in the committee, and I should apprehend that there ought to be no difference of opinion in the Council, because the clause merely recommends what is provided by the Medical Act for the supervision of the licences at present granted. The last paragraph on the page is one which includes one or two principles of importance. I will read the first sentence: "As to other than mere legal difficulties which prevent women from accomplishing their wish to engage in the practice of medicine and surgery, the Council are of opinion that such difficulties must be overcome by private exertions, and that no special legislation is called for, except, perhaps, in the case of midwifery." We found that all those questions connected with the providing for the education of women, and providing schools and teachers for them, should be left, as in the case of male medical students, to private exertions. I understand, for example, that in London all the hospital schools are organised and kept up by the private exertions of those that are particularly interested in them; and we felt that the women and their friends might fairly be asked to undertake all this part of the necessary work for themselves. The last clause of this same paragraph is one of very considerable importance. "Moreover, the Council are of opinion that any course of legislation which would interfere with the free action of the universities and corporations mentioned in Schedule A, in respect of the medical education of women, is undesirable." I think that if this clause be adopted, I should suggest a little addition to it. I would suggest the addition of the words "examination and licensing" after the words "medical education," so that it would read, "in respect of the medical education, examination, and licensing of women." We felt that there should be nothing done by the Legislature to interfere with the free action of corporations in this particular. Then the last part of our report is one which bears upon the question of a special Register, especially in connexion with recognising the competency of women to practise midwifery. I think I am right in saying that this last paragraph embodies very much the spirit of the report of the committee presented to the Medical Council in the year 1873, of which you, Sir, were the chairman; and it was with special reference to the report of this committee that the last paragraph was inserted by us in our report. It was the intention of one member at least of the committee that we should have a clause authorising a copy of this report to be sent to the Lord President, along with the communication from the General Medical Council to be made in reply to Mr. Simon's letter; and perhaps, if the Council should decide upon adopting this report, which I am now submitting to you, we may add to it a clause authorising the report of the committee to be forwarded. Such, Sir, are the remarks which I have to make in connexion with the report which I have now submitted to you.

Mr. QUAIN seconded the motion, which was put and unanimously carried.

Mr. TURNER then moved "That the Medical Council approve of the report of the committee on Mr. Simon's letter."

Sir WILLIAM GULL seconded the motion.

Dr. ANDREW WOOD: If we carried this motion, then there would be no means of amending certain clauses of the report. I think if we could come to some sort of arrangement by which we shall adopt the principle of the report and then go into committee upon the clauses *seriatim*, that would be the better course.

Sir **William Gull** suggested that the Council should resolve itself into a committee to consider the report.

Mr. **Turner** said, that in that case he would withdraw the first motion and move "That the Council resolve itself into a committee to consider the report on Mr. Simon's letter paragraph by paragraph.

Dr. **Storrar** said he presumed that now was the proper time to move the amendment which stood in his name:—"That the duties to which the General Medical Council are appointed are defined by the Medical Acts, and the Council consider that their appointments do not empower them to represent to the Government any authorised opinion on the large social question of the expediency or otherwise of admitting women to practise medicine." He said: The observations that I shall make will be very much shortened by omitting the reference to the greater part of Professor Turner's speech, except so far as to say that I doubt very much whether I differ from him as to the views which he has expressed. My opposition to this report does not arise from any essential difference of opinion from him as to the proper function of women, but from a difference of opinion as to the expediency of the Council taking up this question at all. My view of the matter is that this Medical Council is a corporate body acting under a common seal for definite purposes. What are those definite purposes? They are defined by the Medical Acts. Certain persons were appointed by the Queen and by the various medical bodies to administer these Acts; and what we are to administer is contained in the body of the Act. The points are very few: they are, chiefly, the registration of medical practitioners, with the power of omitting names from the Register, the power of supervising the education of medical practitioners, and the authority to make a British Pharmacopœia. In these three, with very small exceptions, are comprised all the duties of this Council, and I apprehend that we have no capacity whatever to discuss any question outside the area of these matters. The medical bodies that send us here reserve to themselves the duty of deciding, if they choose, upon questions that are not within the scope of these Acts, and we have no right to enter upon their province. Take my own case. I speak of it because it is the one with which I am most familiar. I represent the University of London, and I am the representative to administer what is contained in these Acts. But, Sir, we have had this woman's question up before the University of London, and the popular house passed a resolution in favour of admitting women to the degrees; but the Senate, which is the administrative body of the University, have decided that they will not take any steps to enable them to confer any degrees upon women. The question therefore is so far decided as regards the University of London; and the members of the Senate of the University of London may fairly turn round upon me and say, "What right have you to take up this, or to take a share in the settlement of a question, possibly in an opposite direction from the settlement which we have made, when we in fact, so far as we are concerned, have settled this question already." It is on that ground that I propose this amendment. I feel that we, as a Council, are not here as a promiscuous body, thrown together to fire at every object that happens to be thrown up in the air; but we are here for a definite object, and nothing can be more distinct than the duties assigned to us. But, Sir, it seems that some members of this Council are impressed with the honour of the distinction that has been conferred upon them by the reference of this question by the President of Her Majesty's Privy Council to us. Sir, I cannot say that I entertain so strong an impression of the distinction conferred upon us by the reference. I cannot help recollecting all that has transpired in past years between us and the Privy Council office. It would be a long story to go back to all the transactions that have occurred between us and successive Governments, but I will only go back to the time when we were discussing a Medical Bill which the Privy Council undertook to carry through Parliament. They did carry it through the House of Lords, and they withdrew it in the House of Commons. And they have shown a disposition to push us aside on every or any occasion when we happened to appeal to them on this particular subject. I am sure that you will recollect that two or three years ago we waited upon the Marquis of Ripon to ascertain whether he, as the head of that department, was prepared on the part of the Government to introduce a Medical Bill. We were kept with him for the better part of an hour, and I think that you will agree with me that when we were outside the room on the pavement we knew just as much of the intentions of the Government as we did when we entered the room.

Dr. **Parkes**.—When was that?

Dr. **Storrar**.—About two years ago.

Dr. **Parkes**.—After the withdrawal of the Medical Bill?

Dr. **Storrar**: Yes: and we found it utterly impossible to ascertain from the Government what the intentions of the Government were. All these difficulties have spread over a series of years. Governments have changed. At one time it was the Duke of Marlborough in office; at another time it was the Marquis of Ripon; and now it is the Duke of Richmond. But, Sir, whatever government may be in office, and whatever the source of authority, whatever has been communicated to us has passed through the same channel. The letters have always been signed "John Simon," and whatever may be the source, it is impossible not to see that views of the Government have received peculiar expression in passing through the channel of communication. In whosesoever hand the department has been we can see that though the hand is Esau's, the voice is Jacob's. I must say that I am not one of those who are impressed with the sense of honour which has been conferred upon us by the reference of this question to the Council. I look upon it in quite another light. I look upon it as a Trojan horse. It contains the elements of disputation in this Council; and I can very well conceive the persons in the Privy Council saying among themselves, "What are we to do with this Bill of Mr. Cowper-Temple? The House of Commons is not very clear about it. The country is not very clear about it. Nobody seems to have very definite ideas about it. It will be a nice bone of contention to send down to the Medical Council. Let them worry over it for a few days." We have worried over it, and we have got no less than three reports out of a small committee, and Professor Turner speaks of the difficulty that he had in the preparation of the report. In these difficulties I sympathise with him heartily. Now, Sir, what I feel is that if once we get into the entanglement of a discussion on this great social question, with which in my opinion we have nothing to do, we shall find ourselves, probably, at loggerheads with the bodies we represent here—the universities and medical bodies. They will ask us what right have we to supersede them. What authority, for instance, have we got to step in and exercise a function which is no function assigned to us under the Medical Acts? And they will think that they have got a right to an independent opinion upon it. I confess, I could not defend myself against a charge of this kind. Then as regards the point itself. If we decide in favour of the admission of women, the chances are that we shall have a very considerable number of persons finding fault with us, laughing at us, discussing the matter with us, and, as I say, telling us that we are interfering with matters with which we have no concern. On the other hand, if we decide against the women, it will be said of us as has been said already, "Of course you decide against the women because you are a trades union." That is the remark that has been made, and, I suppose, will be made again. But from the commencement—from the year 1858 to the present year—we have kept clear from these subjects. We have never questioned the right of women to be registered if they will produce the certificate of any of the bodies that we are authorised to recognise. There is Rhoda Garrett Anderson on this Register, and Miss Blackwell, and there may be many others. Let me make my position clear in another respect. I do not call in question the great propriety of the Privy Council appealing to us as to what is to be done with regard to the registration of foreign degrees. That is another thing. Apart altogether from the admission of women under these degrees, the question of registering foreign degrees is one regarding which there is a good deal to be said; but I am anxious, as far as my own views are concerned, to condense them as much as possible. There are many points into which I might diverge; but I am exceedingly anxious to take my ground upon principle, and simply to state, in the narrowest possible terms, what that principle is. I beg, therefore, to propose this motion.

Dr. Parkes.—I do not think it is fair to the Marquis of Ripon that the statement of Dr. Storrar should remain without my saying one word. You will find on page 202, volume 10 of our Minutes, the answer to the deputation. What took place was shortly before the Medical Bill, which was introduced by the Marquis of Ripon, had been dropped by the House of Commons.

Dr. Storrar.—It says:—"The deputation appointed March 28th to ascertain from the Government whether they are willing to aid the Council in the removal of any legal difficulties that may exist in carrying out the objects of Clause 19 of the Medical Act, reported that they had waited, by appointment, on the Marquis of Ripon, Lord President of H.M. Council, and that two other Cabinet ministers, Earl Granville and Mr. Bruce, Secretary of State for the Home Department, were present at the interview, and took part in the conference. That the conference lasted an hour and a quarter. That there was no difference of opinion as to the desirability of the medical authorities in each division of the kingdom combining their examinations, so as to reduce the number of entrances into the profession; but the Lord President was not disposed to introduce into Parliament, for this purpose, a measure which would be limited to conferring on the medical authorities a merely permissive power to combine."

Dr. Andrew Wood.—Go on.

Dr. Bennett (reading).—"His lordship was favourable to the introduction of a measure of this limited kind by some private member of Parliament, but with the understanding that it would not preclude his consideration of a larger measure if, on further thought, he should find it expedient."

Dr. Storrar.—Precisely so. He simply said, "Take what course you please, and I shall reserve to myself the right of opposing or supporting"; so that it amounted to absolutely nothing.

Dr. Parkes.—I submit that that is very inconsistent indeed with the statement that Dr. Storrar just made about the Marquis of Ripon.

Dr. Thomson.—In seconding Dr. Storrar's motion, it is not my intention to offer any observations upon the wide question that threatens to come before the Council, but merely to explain the grounds upon which I rise to second the motion. He has so clearly explained those grounds that I may say, in the first place, that I thoroughly agree with him in the reasons he has given showing the propriety of such a motion being introduced at this stage of our proceedings. I do not think it comes within the province of the Council to give any general declaration upon the subject which has been proposed. I think it is altogether beyond the province of the Council to express, either for themselves or, as it might appear, for the profession at large, any opinion on this subject. The admission of women to the rights of practitioners is a question that can only be settled by the licensing bodies or by the Government. If it cannot be settled by the licensing bodies, then it is a larger question that must be settled by the Legislature. I do not pretend to say by which. I have no hesitation in seconding the motion because I think this is a stage at which it should be brought forward. At the same time I should like to say that in any answer which is given to the letter of the Lord President the utmost courtesy should be shown to the Lord President and to Mr. Simon. I quite feel that the motion in its present state does not meet all that is required. I am aware that an answer must be given to that part of the letter which refers to the registration of foreign degrees; and I hope that in the course of our proceedings such a motion may be framed as will combine the sense of Dr. Storrar's motion with that amount of courtesy which I am sure we all desire to show to the letter from the Privy Council.

Dr. Rolleston.—I have listened with pleasure to what Dr. Thomson has said. He has taken a large view of this matter. If it is to be settled by the Legislature it cannot be settled by the licensing bodies. Now, since 1858 the licensing bodies have taken no step whatever. Between that time and 1875 public opinion has been declaring itself not only by means of clever and able writers who (following the method adopted in this country) do not sign their names, but by others who have forced their names upon the public, and through the public upon the Legislature. We have had, for example, Mr. Mill's book on the subjection of women, one of the wisest and best books that he has written; and that is the sort of reasoning that we have to deal with; that is the sort of reasoning that influences the Legislature at the present moment. And what is the Legislature going to do? Is it going to act without advice? Will it take the advice of these clever writers, or, as Sir Wm. Gull suggested to me, is it coming for coun*sel* to the Coun*cil*? It wishes to act upon the best advice; it is acting with more wisdom in the matter than some other Governments have done; it wishes to get advice from the very best source. I feel very strongly that the Council should not run away from what is its duty. I care comparatively little whether it says yes or no upon this question whether a couple of dozen females shall have what some think justice done to them; but I do say that it would be a slur upon the Council if it failed to consider the question and give its opinion respecting it. With reference to what Dr. Storrar has said, I used to think that the older universities had practised the art of how not to do it. We have rather dropped that art during the last ten or twelve years.

Dr. Storrar.—So it seems.

Dr. Rolleston.—Let me remind the members of the University of London they they owe their *raison d'être* to the way in which we practised that art. We refused to do justice to one-half the males of this country—the dissenters—and the result was that the London University was established. Now some persons are refusing to do justice to one-half of the human species.

Dr. Storrar.—It is assumed that we are doing them justice.

Dr. Rolleston.—That is an assumption of which I shall speak presently. With reference to this matter, let me say that if the London University sends here its representative—whom, by the way, it can scarcely call a representative—but rather a delegate——

Dr. Storrar.—I am not a delegate.

Dr. Rolleston.—If you are tied down in the way you are suggesting you are scarcely a representative.

Dr. Storrar.—I am elected, in the highest sense of the word, to exercise my judgment on matters that form the proper function of this Council, but I have no right, by delegation or election, to deal with any other matters.

Dr. Rolleston.—I am sorry I cannot entirely agree with Dr. Storrar in that matter either. If you will look at the able report of the committee, you will see it says: "Moreover, the Council are of opinion that any course of legislation which would interfere with the free action of the universities and corporations mentioned in Schedule A, in respect of the medical education of women, is undesirable." Now, whether the London University chooses to do what we did a generation ago—that is, not to do it,—or do what I believe the older ones will do now—that is, do it,—it will make no difference one way or the other; but it is a serious matter entering upon this line of not doing things, unless they have something absolutely wrong about them. Holding your tongue when you are asked to speak is one of the very worst things you can possibly do. If we older bodies had not studied the art, I am sure we should not have had a representative of the London University present at this board, for there would have been no London University but for our refusing to do justice to one-half of the Queen's subjects—that is, the dissenters. Now, let me say what I have to say. "Strike, but hear," should be our motto. We know that this proposed admission of women has been tried elsewhere. Again, we know that we had such a person as Queen Elizabeth; we know that we had such a person as Queen Caroline (the first, not the second); and we know that we have at this time Queen Victoria on the throne of this country. Nevertheless, women are totally unfit; their brains are smaller. Prof. Turner omitted to add, their bodies also; and we know that there is a good deal of relation between the size of the brain and the size of the body. Let us say all this if we like, but do not let us run away from our duty. Let us take for our motto that of the fine classical novel of "Ivanhoe," "*Adsum, cave!*" Do not let us run away, but let us do the duty that lies before us.

Dr. Thomson.—In consequence of what has fallen from Dr. Rolleston, I wish to say that in seconding Dr. Storrar's motion I did not express any opinion one way or the other; that will be for the future.

Sir Wm. Gull.—I think the whole of Dr. Storrar's argument falls to the ground when I consider why am I here. Why is Dr. Stokes here? Why is Dr. Sharpey here? Why is Dr. Parkes here? Why is Dr. Quain here? Whom do we represent? Where do we get our authority? If we have none, why has Dr. Storrar any? If he has none, neither have we. It seems to me that that consideration cuts away all the ground from him.

Dr. Storrar.—You have no power beyond ours.

Sir Wm. Gull.—That is what I wish to be understood. But I wish you to take a larger view of your own powers. You have taken too narrow a view; that is the fault you have committed. According to your views, as Dr. Rolleston has said, you are rather a delegate than a representative.

Dr. Storrar.—No.

Sir Wm. Gull.—I cannot take the position of a delegate, for I have nobody to delegate me but the whole country. I have to consider what are my duties to this country at this Board. Dr. Storrar says our duties are alike.

Dr. Storrar.—They are.

Sir Wm. Gull.—Then you are to consider your duties to the whole country at this board, and not merely your duties to the London University.

Dr. Storrar.—The two must go together.

Sir Wm. Gull.—What defines my duty equally defines Dr. Storrar's. We are not delegates at all. We come here to give counsel on the great affairs of this country with respect to medicine and medical practice. That is the view I choose to take. I am not sent here merely to act the part of a policeman, which I dare say any tolerably respectable man at £3 a week could do as well as I could, and perhaps a great deal better. The Government have taken me from my important duties, to do what? Not to do next to nothing; they have sent me here to consider the whole question. I read in the first line of the Medical Act: "Whereas it is expedient that persons requiring medical advice should be enabled to distinguish qualified from unqualified persons." The Register is only subordinate to that. It is for us to consider what the Register shall include.

Dr. Storrar.—The schedule tells you that.

Sir William Gull.—Dr. Storrar seems to think that the Register can only be of a certain character; but I think that the Council is here to determine what that Register shall be, what shall be its extent, and what the conditions under which people shall be put upon it. That takes in the whole question whether it is expedient for women to look to medical practice as a means of livelihood; and if they may so look, then we shall consider the conditions upon which they shall be put upon the Register. The Government has sent representatives here having equal power with other members; and therefore our duty is to the country above all things, and not to the corporations: our duty is to help the public to determine who are fit persons to consult; and if the public say, "we wish to consult women," we are bound to consider under what conditions they may consult them safely. If that be not consecutive and logical I am inconsecutive and illogical. If that be the fact, we cannot escape from our duty. What is the meaning of the word Council? I ask the President if he can tell me the scope of it. If this is a Council, surely it has some function beyond looking after the registration of these people. Dr. Storrar says the Government has not treated us well. Then let us give them good for evil. Let us be ready to offer them the best of our services in the best way we can, and they will treat us better in future. I cannot see that that is any argument. Then he says that the letter has come from Mr. Simon. Well, let it be taken *quantum valeat*. I have an intense personal respect for Mr. Simon.

Dr. Storrar.—So have I.

Sir Wm. Gull.—I do not know why his name should have been introduced. We are bound to consider the letter as coming from the Privy Council. The Lord President said to me to-day—I am at liberty to use his name—"I am much interested in the matter [he knew we should be discussing it], and I shall be happy to confer with the Medical Council at any time they may desire." So that you see the Government is interested in this question. This is not a corporate question at all. The report states that the corporations should be left free to do as they like. It is said that we ought to inquire what the profession has to say. Does any man pretend that he does not know what the profession will say? It has been discussed again and again. I should like to know how you will get at the voice of the profession. How can it be got at better than it is at present? We have the public journals, and the whole thing has been discussed there. We have talked of it on all occasions. Does this Council represent the profession or not? If it is a representative Council of the medical profession, let us act for ourselves and not adopt the policy which was referred to yesterday—the policy of waiting and putting off, and going back to the corporations. I say if I am here for any purpose I am sent by the Government to fulfil a large and important duty, to give the advice to the Government that they may ask for in the best way I can, and to take as large and constitutional views of the whole question as I can. We are not sent here for the mere limited purpose of keeping the Register as it now stands. We ought to enlarge that Register and help the public in every way we can to know whether they are consulting qualified or unqualified persons.

Dr. Quain.—There are two questions before us—one a question of law, and the other a question of expediency. No one can doubt that Dr. Storrar is perfectly right in saying that by law we have no right to express any opinion such as is asked of us. ("No, no.") Our duty is to carry out the Act of Parliament. Then there is the question of expediency as to whether we should send a suitable answer to the question that is put to us. I agree with every word that Dr. Storrar has said, but I shall be obliged to vote against him, because I think it is expedient that we should give an answer to the question. There is only one other word I wish to say. I cannot understand why the question of delegates or universities should be introduced. Dr. Storrar never said a word about it.

Dr. Rolleston.—He spoke of the London University.

Dr. Quain.—He merely asked what right we had to express an opinion about the functions of those bodies.

Dr. Rolleston.—He said that the Senate had opposed it, but that the popular body had voted for it.

Dr. Quain.—Considering the expediency of answering the President's letter, I shall vote against Dr. Storrar's motion. I do it with regret, because I think that he is right.

Dr. Wood.—I shall vote against Dr. Storrar's motion for a different reason, and that is because I disagree with every word he has said. I consider that we are not sent here as delegates by anybody. I would not sit here as a delegate. When my college appoint me to come to the Council, they leave me at perfect liberty to deliberate upon all matters coming before the Council; and if they are not pleased with the way in which I do that, they can act upon their own judgment and turn me out, and put in somebody else. Therefore, I do not consider myself a delegate; I consider myself a representative, and I believe this Council to be a representative council. If it is a representative council, what does it represent? It must represent the medical profession. We are all medical men here. We are all sent in the interests of the public in order that the public may get the best medical aid that can be got. I am astonished that a slur should be thrown upon the Government because they come with a courtesy and kindness and a deference which I am glad to see, and ask us for our advice. There have been occasions when they have not treated this Council with the deference they deserve. "But many things have happened since." When the Duke of Richmond, who was most anxious to do what is right, asks our opinion, why should we not give him an answer? He may ask the opinion of anyone. He may go and ask the opinion of Miss Jex Blake if he likes. He may ask the opinion of the Royal Society, or of any other body whom he wishes to consult. But he says "Whom shall I consult with the greatest hope of getting good advice? Shall I not consult the men who are assembled in London at this time, and who represent the medical profession?" And shall we say to the Duke of Richmond, "Oh, your Grace, we are much obliged to you for communicating with us; but really we decline to give you an answer upon the subject, because, forsooth, it is not within the clauses of the Medical Act that we are to give advice to the Privy Council upon the education of women?" I say when a great revolution is threatening our medical profession—for I consider the introduction of women into it would be a great revolution,—and when it is pressed upon the Government to take up this question, and when the Government are anxious to have the best advice before taking any steps one way or the other, shall the Council say, "Your Grace, you have asked our opinion; we will give you no opinion; we are a mere Council for registering practitioners, and therefore we do not consider ourselves a Council to whom you should refer?" Sir, I am thankful to the Duke of Richmond. He has treated us with the utmost courtesy—he and the other ministers—the Marquis of Ripon among the rest—and we ought to give them the best advice we can. We are not to be considered the infallible advisers of the Government, but the Government will consider the arguments we lay before them, and if they approve of them they will adopt them; if not, they will reject them. I hope the Council will not adopt the motion, because if it does it will lose an amount of influence which can never be restored.

Sir D. CORRIGAN.—With a very slight alteration in Dr. Storrar's resolution I should feel bound to vote for it, although I consider the motion of which I have given notice is very much better. I quite agree that we are not authorised to take up this question. Dr. Storrar says that we never could take it up; but I do not go so far as that. For myself, I feel that I am not justified in coming here to decide upon so important a question without going back to my constituents and consulting them as to what are their opinions. What I therefore propose is that the answer should be deferred until we have had time to consult our constituents. Dr. Wood has said that we ought not to delay, and the same doctrine has been preached by Mr. Turner. It amounts to this: the Government has treated us badly for a series of years. It has snubbed us; there is no question about it. They would not tell us what they were going to do, and now that they evince a desire to throw themselves into our arms, forthwith we are to accept their repentance and suddenly answer the question that is sent to us. I cannot assent to the proposition that we are to answer the question suddenly without consulting our constituents. Dr. Wood has said that we are representatives of the profession. Technically speaking we are not. We are representatives of nineteen licensing bodies, and there is a wide difference between representing the profession and representing those bodies. You know that there has been a struggle going on for many years between the British Medical Association and this Council with regard to getting admission to this body. I do not want to take one side or the other; but I say technically we are not representatives of the profession. The question is a very important one, and it has been decided on by a committee which I must observe was not at all unanimous. We differed on nearly every proposition, and we are called upon now suddenly to bring forward those propositions, every second one of which is inconsistent with the one before it. I regret that I must vote against Dr. Storrar's motion, although to a certain extent I agree with him.

Mr. MACNAMARA.—Clause 18 enables us to take into consideration generally the requisites for obtaining qualifications. It seems to me that that entitles us at the present moment to take into consideration whether being of the male or the female sex is requisite for the licence.

Dr. SHARPEY.—In voting upon this occasion—not that my vote will count for much—I must vote against Dr. Storrar's motion. I heard with some pain the introduction of the word "delegates" as applied to members of this body. I have had the pleasure of sitting on this Council many years now with Dr. Storrar, and I must say that the whole tenor of his conduct and proceedings in this Council has been anything but that of a mere delegate. But let that pass. My reason for rising is to point out to Dr. Storrar that he is mistaken in supposing that our function is restricted to the carrying into effect the provisions of the Medical Act, because we are frequently called upon to propose amendments under the Medical Act, and we have again and again proposed amendments of it to the Government. That is quite a different thing from merely carrying into effect existing provisions. I beg to remark further that in the report which was read and commented on by Mr. Turner, there are proposals which would involve amendments in the Medical Act. The report proposes that certain additional powers should be granted to the Council—powers which they have not now under the Medical Act. I think, therefore, that the technical objection of Dr. Storrar is not sufficient. Independently of the question of expediency, I think it quite competent to give an answer to the Government on the question which they have submitted to us. Sir William Gull has very properly pointed out that some of us are not directly commissioned by any Act of Parliament in the kingdom, but are understood to represent here the public interest. No doubt it is understood that we all do that more or less directly, and I think we should be shrinking from an important duty to the country if we declined to aid the Government in this matter.

The amendment was then put and lost.

On the motion for the adoption of the report,

Sir D. CORRIGAN proposed the following amendment:—"That the following letter be forwarded to Mr. Simon in reply to his of the 8th June." To the questions which Mr. Simon asks concerning Mr. Cowper-Temple's Bill, I think there is not a second opinion in the Council. I know that on the committee we were unanimous in the opinion that the Bill would admit on the Register the names of women with foreign degrees given by universities over whose course of education and examination we have no control whatever. While the men are denied the privilege of having these degrees recognised, women are to have that privilege. That part of Mr. Simon's question I consider to be decided; and I may state that that part of my proposed answer which conveys our views with regard to his letter coincides with the reply in the report of the committee which Prof. Turner has read. The portion of my reply which I refer to is—"The first part of the letter expresses a desire that His Grace the Lord President of the Council should be favoured with the views of the Medical Council on a Bill introduced by Mr. Cowper-Temple to amend the Medical Act of 1858 so far as it relates to the registration of women who have taken the degree of doctor of medicine in a foreign university. In reply thereto, I am directed to observe that the Council cannot approve the Bill, seeing that it would propose to confer on women the privilege of registering foreign degrees, from which privilege men under the Medical Act, 1858, are excluded, and in the opinion of the Medical Council properly excluded, for this reason, that the Medical Council has no means of exercising over foreign degrees and their holders the supervision and control to which all the licensing bodies of this country, universities, and corporations, and the holders of their degrees and licences are subject under the Act of 1858, which supervision and control are most necessary on social, moral, and professional grounds." On that question we are all agreed. With regard to Mr. Cowper-Temple's Bill, I believe the sentiment here is in strict accordance with the views of the Medical Council. Now, the next question raised in Mr. Simon's letter is that of general practice—that is, whether women are to be entitled to look to general practice as a means of livelihood, and of course to be registered. And then he puts a question which, I think, has been ignored in the report of the committee. He puts the question whether they are to be admitted to general practice, and then the question as to whether they are to be admitted to certain branches of it. I do not think this last branch of the question is sufficiently and distinctly dwelt on in the report. The last part of the letter to which I will direct your attention is this: He goes on to inquire what are the conditions with regard to women who desire to obtain legal status as medical practitioners in this country; and, on the other hand (I will ask your attention to this), to the "examination rules or other conditions which prevent them from accomplishing their wish." Now there is not a single word in the answer with regard to that. He simply asks you for information as to the conditions or circumstances which prevent them from accomplishing their wish. And what is our answer? Why the report of the committee passes that by, and it says, "In order to accomplish their wish such and such regulations ought to be passed." That is not an answer to the Lord President. The Lord President, or Mr. Simon for him, asks what are the conditions which prevent women from accomplishing their wish, leaving to the Lord President and the House of Commons to devise what are to be the means by which those objections are to be removed, or what course the House of Commons might follow. But instead of informing the Lord President as to the conditions which prevent women from accomplishing their wish, the report of the committee passes that by totally, and simply lays down a plan for the Government, by which they may be enabled to gain admission. The Lord President asked one question, we have answered another question which has not been put. He never asks us in that letter what are to be the means by which these objections or obstacles are to be removed; he simply asks the question, "What are the examination rules or other conditions which prevent them from accomplishing their wish?" and that question we have passed over completely, for we have not acquainted him with what are the conditions which prevent them from accomplishing their wish. Now, this forms in my mind a very serious objection to this answer from the committee, for I think it is a very good rule that you should answer as fairly and as fully as you can the questions asked, but I do not think it is a proper course to evade a question asked and give an answer to a question that is not asked. The Lord President has not asked us what is the Parliamentary measure that he ought to introduce, or what is the Parliamentary measure that we should recommend; he has asked us no such question, and yet we have gone into the question of what it ought to be and what the House of Commons ought to do. Now, this, I think, is the most serious objection to the whole answer and the whole course proposed by the committee. The letter of the committee says: "In reply to the communication addressed to them by the Lord President of the Privy Council, the Medical Council beg to state that, being thus directly appealed to by the Lord President, they have felt bound to consider the question of admission of women to the medical profession." I feel myself bound to consider it, and in that I differ from Dr. Storrar; but I am not bound to consider it on so short a notice as twenty-four hours, and without consulting the University which I have the honour to represent. In my answer I do not propose at all that we should evade the question; I simply propose that we should have an opportunity of going back to our constituents to put the letter of the Lord President before them, and then, armed with their opinions and their views, give an answer. It is said by Dr. Wood that we ought to give an answer immediately. Well, how long have we had a conjoint scheme before us? Three years, and we have not felt ourselves bound to give an answer up to the present. Now there comes before us from the Lord President, and very properly, a most important question—first, as to Mr. Cowper-Temple's Bill, on which we have given an answer, because we know distinctly the opinion of the whole profession on the point; and next, with regard to the other bodies admitting women; and next with regard to their entering certain branches of the profession. I cannot think that the Lord President, who knows of what consequence it is to have due deliberation, even upon the most minor considerations that come before the House of Commons, would hurry us, or should be imagined to hurry us, into a decision upon that very, very important question. Now we come to an opinion expressed—and it may be right or wrong; but I do say that we have come too suddenly to it. It is in paragraph 2 of the report of the committee. It says, "After due deliberation the Medical Council have to express their opinion." What is due deliberation? The report is only put before us to-day.

Mr. Turner.—Yesterday.

Sir D. Corrigan.—Well then, yesterday. How do you call that due deliberation? I think, after the many avocations which we have had to go through in London in relation to professional questions, and the hospitality which has been exercised towards us in London, we have been unable to give the matter due attention. Now, the next paragraph to which I have to draw attention is one which ought not to be adopted. "Instead of medicine offering more facilities and less difficulties for women than other professions, the Medical Council believe, that as the whole question is looked into, there will be found peculiar hindrances, moral and physical, to the successful pursuit of medicine by women. Moreover, they desire to add that if it be admitted that women should enter the medical profession, the existence of an equal fitness in women for other professions must be assumed." I do not think that that is common logic. Are we to assent to such a ridiculous proposition as that, if we admit women into the medical profession to study medicine and practise it, therefore, forsooth, a little girl of thirteen or fourteen may be sent as a "midshipman" on a ship of war? That paragraph appears to me to be utter nonsense. Then it says, "If, notwithstanding such objections, it should appear expedient that women should not be debarred from obtaining that status." We have in the paragraph a few lines before this a statement that "There are special difficulties which cannot be obviated."

Mr. Turner.—The report says, "Some of which objections cannot be obviated."

Sir D. Corrigan.—It is all the same to me whether there is one objection which "cannot be obviated" or three or four; it makes no difference. If there is one which "cannot be obviated" women cannot enter the profession. "If, notwithstanding such objections, it should appear to the Government and the legislature expedient that women who desire to obtain a legal status as medical practitioners in this country should not be debarred from obtaining that status, the Council recommend that it should be under some such condition as the following." Now that, converted into plain English, means, "If the members of the Government should make fools of themselves and pass a ridiculous Act of Parliament, we will make ourselves parties to it." There is a suggestion on the part of the Chairman of the Committee that we ought to meet the Government half way.

Mr. Turner said he did not use that expression.

Sir D. Corrigan.—No, it was I who introduced it. Now I think that instead of aiding the progress of a measure which we have distinctly stated is objectionable on "moral, professional and social grounds," and as to which there are difficulties which we have said "cannot be obviated," the more straightforward, manly, independent, and proper course is this—that, instead of the paragraph which I have read, we should say that, "Having expressed our opinion so strongly upon women pretending to go into the profession of medicine, and considering that there are special difficulties which cannot be safely ignored, and some of which cannot be obviated, it is our duty, as men who are advocates of social order and propriety, to say to the Lord President that we are obliged to decline being parties to any compromise or to any measure that would admit women into the practice of the profession." That appears to me to be our proper course. Now we go on to say "That in the interests of public order, the education and examination of female students of medicine should be conducted entirely apart from those of males." The second condition is "That with regard to 'the examination rules or other conditions,' which prevent women from obtaining a legal status as medical practitioners in this country, it would be sufficient if an Act of Parliament were passed which should enable the Medical Council to recognise the examinations of the licensing bodies under Schedule A of the Medical Act, separately or conjointly, or such other examination or examinations as the Medical Council may from time to time deem sufficient for the purpose of granting admission of women to the Medical Register under the title of 'Licensed Practitioners of Medicine.'" Now there are to my mind two objections which cannot be got over with regard to that paragraph. In the first place, we take up a question which has not been asked at all, and we give the Government advice as to what they are to do. The Government does not ask us for it. The Government has simply asked us to state for their information what are the conditions which at present impede the way of women who desire to obtain a legal status as medical practitioners in this country. That is the only question that they have asked on the point, and we have evaded that question and advised them to pass an Act of Parliament. Now let us come to this wonderful Act of Parliament. We have been for years working on a conjoint scheme. Well, I think all our exertions in that way have not hitherto been successful; but, what are we now proposing? It is to pass an Act of Parliament which, to say the least of it, will make three or four examining bodies in addition to those already existing; so that we are blowing hot and cold. We are saying, on the one hand, that the licensing bodies ought to be diminished in number, and here is a proposal that the Government should give this Medical Council, on certain conditions, power to grant admission to women (I am quoting from Condition 3)—it proposes to grant admission to the Medical Register, and the examination is to be "such examination or examinations as the Medical Council may from time to time deem sufficient." Do you think that if that were admitted, three months would pass over in London, or Dublin, or Edinburgh, or Glasgow, or any such places, without the women coming forward, having a meeting in St. James's Hall, or somewhere else, and saying that they were not fairly treated—that they did not get proper examinations? Now we come to Condition 3: "That the examinations of female candidates for a licence entitling their names to be placed on the Register should be of the same character as those of males." If that means anything at all it means that it should be the same examination. But at the middle of page 7 we find an observation that is utterly inconsistent with it. It is that "The Council believe that the education and examination of persons with such views" (that is with a view to practise midwifery) "will not be found to differ greatly, upon the whole, from those required of candidates for ordinary licences to practise." "Nevertheless, women might be fit for registration on a special register without passing an examination in various parts of surgery, and indeed of medicine." Now it is impossible that those two things should stand. One says that the examinations ought to be of the same character as those of men, and the other says that women might be fit for registration on a special register, without passing an examination in various parts of surgery, and indeed of medicine. I now go back to a paragraph that I do not understand at all. "As to other than mere legal difficulties which prevent women from accomplishing their wish to engage in the practice of medicine and surgery, the Council are of opinion that such difficulties must be overcome by private exertions, and that no special legislation is called for, except, perhaps, in the case of midwifery." But you have not stated what those difficulties are. You say, "other than mere legal difficulties." I do not know any other than legal difficulties; I do not recognise anything but legal difficulties; nor does this paragraph point out in what direction the special exertions of women are to be directed to attain the end in view. I think it a very confused sentence, and one unworthy of this Council. Now, Sir, I have shown, I hope, sufficient reason for the course I have taken in criticising this report, paragraph by paragraph. I do not think that it is a report worthy to go before the Lord President and the Privy Council; I do not believe that it is a report that can be amended so as to make it, as I have said, worthy of us. I believe that if my amendment is thrown out, the proper course would be to withdraw the report altogether. Now my letter goes on, in the first place, to answer the first question, which relates to Mr. Cowper Temple's Bill. Then, I say, "The second part of your letter resolves itself into two questions:—Firstly, whether women ought to be able to look to medical practice, or certain branches of it, as open to them equally with men as a profession and means of livelihood?" The branches are not enumerated, but the question as to women looking to certain branches of medical practice as open to them equally with men may be considered, the Council suppose, as specially referring to midwifery. Well, I do not know any other branch that may be considered to come under that view. "On this the Council have to observe that, by established usage, women from the earliest times have practised midwifery." The practice of midwifery at all times, so far as we know, has been pursued by women. In Ireland, at the present moment, midwives are licensed by private individuals, and on those licences salaries are awarded to them. I think that this is a very improper course; and if the system of midwives attached to Poor Law medical appointments is continued for the sake of the public, the licences ought to be issued by bodies who have no pecuniary interest in selling their certificates. I will tell you what has occurred within my own knowledge. A man who never attended a case of midwifery bought his licence, I will not say where. He went into the country to practise as a dispensary doctor, and when the first case presented itself he did not know what to do. It was a foot presentation; and when he found the head was in the vagina, and the feet outside, he twisted it round and round till he left the head in the vagina, and had the body in his hand. Similar instances might be multiplied in England, Ireland, and Scotland. That is a thing that has occurred, and it ought to be put a stop to, and we ought to prevent midwifery licences being granted except by the legitimate corporations. I come now to Dr. Storrar's resolution. He says that the Medical Council was appointed under the Act of 1858 to carry out the provisions of that Act. Now I have said, and I say again, that this question never before came before this Council, and yet we are asked in 24 hours to give an answer to it. In 1873 there was a committee appointed to draw up a report on the special education of women, and I think our respected President was the chairman of that committee. They drew up a report. That report never came before the Council. Two years passed away, and yet it is said that we ought at once to give an answer to that important question, while the report of the committee on the same subject has been published and handed about; but the Council has never had the courage to take it up. I hold that we ought not to be asked to decide in a great hurry upon such an important question. My letter continues:—"The Council may in the mean time append these observations. First. They are aware that there exists a diversity of opinion in the profession and among the licensing Universities and Corporations as to the admissibility of women to general medical practice." I know that that diversity exists, for the subject came before the Queen's University, and as a preliminary step we had the opinion of the law officers of the Crown. I cannot say what the decision might have been; but the discussion was stopped in consequence of the law officers of the Crown declaring that we had not the power to give a licence to women. There was a diversity of opinion in the Senate of the University, and there is a diversity of opinion in the corporations; and where that exists I think that we ought to go back to those corporations, and get an authorized statement of their opinions. The next observation I have appended is this—"There appear to exist very great difficulties with regard to the details of education and examination of women desirous of entering the medical profession, on social, moral, and professional grounds; and it does not appear that the Council can at present do more than bring the whole subject under the consideration of the licensing bodies of the United Kingdom, and obtain their views as to the admission of women who may desire to obtain legal status as medical practitioners, or to practise certain branches, and also the information desired by the Lord President as to 'the examination-rules or conditions which prevent them from accomplishing their wish'"—(that is the pith of the whole letter from Mr. Simon, and that we have not answered at all)—"and then forward the communications to the Lord President, with such observations as the Council may deem it necessary to add." Now, does anyone believe or think that there is any very great necessity for extraordinary hurry at this present moment? Does anybody think that either Mr. Disraeli or anybody else will take up this question? Now, when we are almost in the month of July, and after the Government have declined to take up measures of great consequence (such as, for instance, the holiday question and the Brighton Aquarium), is it likely that they will take up the consideration of this matter? I do not believe that the delay will do any harm if we simply pass a resolution that the members of this Council be directed to obtain the views of the corporations on Mr. Simon's letter, and bring those views forward at the next session of the Council. There can be no real delay by postponing it, and if that course were adopted I should have no objection to withdraw my amendment. If the report be persevered in, I shall take the opinion of the Council upon it.

The PRESIDENT.—I think it is my duty to the Council, as having been formerly the chairman of the committee to which Sir Dominic has referred, to state that I feel I owe an apology to the Council for not having prosecuted the matter; but it hardly represents the exact state of the case to say that this report never was before the Council. On the contrary, I find that on the 2nd April, 1873, a motion was carried reappointing the committee, and empowering it to proceed with the subject. It would hardly be desirable that the Council should suppose that nothing had been done, and that this report had not been received. If there were a motion on the subject, I could explain why nothing was done.

Sir D. CORRIGAN.—It stands, then, as I have said—namely, that the committee was appointed in 1873; but the Council never gave an opinion upon that report; they never having had it before them.

The PRESIDENT.—That is not the fault of the Council; it is the fault of the committee.

Dr. AQUILLA SMITH.—I rise to second Sir Dominic Corrigan's motion; and one reason for my doing so is, that it differs very materially from Dr. Storrar's motion which has been discussed. Sir Dominic Corrigan's motion does not ignore the question, and does not take the power from the Council of considering it in future. I concur that it is the bounden duty of this Council, when it has been honoured by a communication from the Privy Council, to entertain the question, and, at any rate, to return a becoming and courteous answer to the head of the Government on any question that could be discussed by the Council. But I also support this motion because I take it that Sir Dominic's object in proposing it is, that his motion should supersede the report that has been received from the committee. I shall not go over the matters that Sir Dominic has so fully drawn the attention of the Council to; but I shall just state, very briefly, my reasons for objecting to the report and objecting to the motion which is now before the chair. I was very much struck this morning by the very remarkable contradictions in the report, contradictions as flat as can be. The paragraphs Sir Dominic Corrigan read, beginning at the bottom of page 41, point out, in clear and strong language, the incapacity of women to compete with men in the medical profession. That is admitted. In the latter part of the resolution the committee suggest that an Act of Parliament should be passed to introduce them into the profession, after expressing, in very clear language, that they believe that women are utterly incompetent to compete with men as medical practitioners. Then, taking that recommendation of the Government, they say, "It would be sufficient if an Act of Parliament were passed which should enable the Medical Council," and so on. Then looking at the 6th paragraph we find, "Moreover, the Council are of opinion that any course of legislation which would interfere with the free action of any of the universities and corporations mentioned in Schedule A in respect of the medical education of women is undesirable." Those appear to me to be such contradictions in the report that I cannot give my sanction to it. To recommendation No. 3 also I have a very great objection, "That the examination of female candidates for a licence entitling their names to be placed on the Register should be of the same character as those of males." I will ask those who are teachers, would they feel themselves warranted in going into the very important and wide subject of syphilis and all its consequences? Would the ladies be instructed in that? ("Yes.") I have reason to know from a document which, by accident, has come into my possession since I arrived in London, that there is one lady who aspires to medical honours who would not shrink from the inquiry into syphilis in its most revolting forms. I have great pleasure in seconding Sir Dominic's motion, because it is an important matter. I take the view of Sir Dominic, that this subject has certainly never been brought under the consideration of the body whom I have the honour to represent, and I should not feel myself warranted in stating an opinion that females should be admitted according to the suggestions of the report.

Dr. ANDREW WOOD.—I beg to recall the attention of the Council to the actual subject under debate on this motion. We have had a long discussion on the report of the committee; but the great question involved in Sir Dominic Corrigan's amendment is that we should tell the Privy Council that we are not ready to give an answer to this question that they put to us, and that we must send the matter down to the licensing bodies. That is the whole question, and I say that a great many of the statements that have been made by the gentlemen who proposed this motion are quite outside the question which they have discussed. Therefore I hope that we shall now go to the vote, and say whether we shall go on to consider this question in the Council, or whether we shall agree that we are not ready to take up the question. The question is not new to me, certainly in Edinburgh; and all through the country there has been nothing going on for a great many years that has excited so much attention as this subject of female doctors. I therefore hold that to go to the Government and say that we have not had time to consider the question, when we have been considering it for years, would be a great stultification. I hope we shall vote without further delay.

Sir WM. GULL.—If we are stopped here we are stopped altogether. This is not in the least a question of corporations or universities; they have nothing whatever to do with it; it is a question for the public, the Medical Council, and the Government. We particularly say in the report that the Medical Corporations and Universities shall be left free, and that we deprecate any interference with their system. Women are outside these bodies. The Government wants to know whether women are to have this freedom that they desire; and what will you do? Go and ask people who have nothing at all to do with the question? The London University has nothing to do with it, unless it likes to take it up. Sir D. Corrigan thinks that he and others who represent corporations have as much power as we have who do not. Then they have power outside their corporations; but to send this question back to the corporations is to admit that there are on this Council members who are nothing but nominees and representatives of different bodies.

The amendment was then put and negatived.

Dr. WOOD.—I shall not intervene between the Council and the committee by proposing what I have put upon the programme, because a large part of it is actually in Professor Turner's report, and I shall have an opportunity in the course of the discussion upon the different clauses of moving any parts of my report that seem to be different from it, and also of discussing the general question, which has not yet been touched on.

Mr. TURNER.—I should like to ask in what position we are placed with reference to Dr. Bennett's motion. If we agree to certain propositions in this report, it then becomes the report of the Council.

Dr. BENNETT.—I see the difficulty. My proposed report is in the hands of the printers, but if it is desired I can read it, so that the Council may know what is to come before it. I assume that our answer will come in the form of a letter from yourself, Sir, to the Lord President; and the letter I propose is this:—

"Sir,—In accordance with the request of the Lord President, as conveyed in your letter of the 8th instant, I have the honour to inform you that I have brought under the consideration of the General Medical Council the Bill which has been introduced in the House of Commons by Mr. Cowper-Temple, to amend the Medical Act, 1858, so far as relates to the Registration of Women who have taken the Degree of Doctor of Medicine in a Foreign University. To this Bill of Mr. Cowper-Temple, as well as to the collateral and wider questions to which your letter refers, the Council have given full and careful consideration. With regard to Mr. Cowper-Temple's Bill, considered by itself, and apart from its bearings on the 'general question whether women ought to be able to look to medical practice, or certain branches of it, as open to them equally with men, as a profession and means of livelihood,' the Council have found no difficulty in forming an opinion. By the Medical Act, 1858, the Council are precluded from granting admission to the Medical Register to persons holding foreign degrees, and, consequently, have been compelled repeatedly to refuse to register foreign degrees held by men. The reason for this is obvious—viz., that the Council have no means of exercising that supervision and control over the education and examination required for foreign degrees, to which the licensing bodies of this country, whether universities or corporations are, by the Act of 1858, subjected. But this privilege, which the Medical Act refuses (and the Council believe, very properly refuses) to men, Mr. Cowper-Temple's Bill proposes to grant to women. To such a proposal the Council feel bound to offer a respectful but decided protest, as being subversive of the main principle of the Medical Act; and, though in appearance of very limited scope, calculated to be productive of serious evils. With regard to the general question referred to, and on which the Lord President desires to have the observations of the Medical Council, they would in the first place remark that it is a very wide subject, and one that appears to them to involve the discussion of very grave questions, moral, social, and political, which appertain to the Legislature, rather than to a Council of Medical Education and Registration. If the Legislature should determine that the learned professions, and, therefore, that of medicine among them, should be thrown open to women as well as men, and that a legal status should be given to women as medical practitioners in this country, it would be the duty of this Council to offer every assistance in their power to the Government in framing rules for the education and examination of women, and in suggesting conditions for giving them admission to the Medical Register. The Council, however, cannot conceal from themselves the serious difficulties that would attend the framing of such rules and conditions, involving, as they would, the peculiar, and in the opinion of many, almost insuperable hindrances, moral, as well as physical, to the efficient education and successful pursuit of medicine by women, and demanding, in the interests of public order, that both the education and examination of female students of medicine should be conducted entirely apart from those of males. The Council have already had their attention drawn to the importance of securing more efficient instruction for women who engage in the practice of midwifery, and whose services are largely employed, especially by the poor of this country. The Council feel very strongly that it is desirable that some means should be adopted for securing a better education, and granting certificates of competency to women who act as midwives. For, whilst fully admitting that for the safe and efficient practice of midwifery as a branch of medical science, a full and complete education both in medicine and surgery is required, the Council believe that a much more limited and less expensive education might be afforded to women, who after due examination might, as midwives, render valuable service to the community, and supply a deficiency long felt and expressed. For women thus educated and certificated, it might be desirable that a special Register should be provided, and which the Council think might be secured by an alteration in Schedule (D) of the Medical Act.—I have the honour to be, &c."

Mr. TURNER.—I would suggest that we suspend the further discussion of this matter till to-morrow, when we shall have Dr. Bennett's motion in type.

Dr. ROLLESTON.—Having listened with great attention to Dr. Bennett's report, it seems to me that it is in many respects an improvement upon that of the committee. Of course it is an easy thing for an accomplished person to improve upon phraseology when he has the *corpus vile* before him. With Dr. Bennett's letter before us, I think we can at once take up the consideration of the report. Let us keep on at full swing; and as each clause is submitted, we can consider Dr. Bennett's amendments.

The Council then went into committee on the report.

Mr. Turner moved, and Sir W. Gull seconded, that the first three paragraphs of the proposed reply to Mr. Simon's letter be adopted.

Dr. Parkes moved that the paragraphs be omitted, because in his opinion they expressed a great deal too much, and yet too little. They did not contain any real answer to Mr. Simon's question, and would very likely land the Government in great perplexity. It was stated that there were special difficulties in the way of women which could not be safely ignored, and some of which could not be obviated, and yet it was a well-known fact that women were practising in various countries. No answer had been given as to what the "special difficulties" really were. No doubt there were certain portions of medical practice in which women would never be able to compete with men, but there were other portions in which, on the whole, he believed they had a superiority over men, specially with regard to diseases of women and children. He thought that the paragraph as to the "peculiar hindrances, moral and physical" to the successful pursuit of medicine by women, was extremely objectionable, and he felt it his duty to vote against it. He also objected to the statement of the report that if women entered the medical profession it must be assumed that they were equally competent to enter other professions—a most illogical conclusion to arrive at.

Dr. Bennett seconded the amendment, and suggested that the different points in Mr. Simon's letter should be taken up in the order in which they were there stated.

After a long discussion as to the form in which the question should be brought before the Council,

Mr. Quain said he would accept the paragraphs proposed by Mr. Turner as a kind of compromise, seeing the opposition there was in the committee to the recommendation being carried, unless they were prefixed with some such statements as those contained in the opening paragraphs of the proposed letter.

Dr. Rolleston, in opposing the motion, said he thought the paragraphs in question should be retained for the sake of unanimity in the Council.

The amendment was put and carried.

It was then moved that the amendment be carried as a substantive resolution; when

Dr. Rolleston moved, as an amendment, that the report be remitted to the committee, and brought up on the following day, and that Dr. Bennett be added to the committee.

Mr. Turner seconded the amendment, which, after some discussion, was ultimately carried and agreed to as a substantive motion.

The Council then adjourned.

BASKET-BURIAL v. GLASS-LID COFFINS.

To the Editor of The Lancet.

Sir,—Mr. Haden's plan of basket-burial lies open to the following objections:—1st. It is novel and repugnant to our present feeling on the subject to be buried in a basket. 2nd. It requires a special manufacture. 3rd. Though cheap now, it would become expensive from scarcity of material, if universally adopted. 4th. It fails in its prime object, which is the speedy decay of the body, especially in those cases where the double basket is used with the lining of charcoal. 5th. Unless the charcoal be used, it would allow a smell to escape in all cases; and in cases of death from infectious diseases would be dangerous to the survivors. 6th. Where the charcoal is used, which in most cases would be necessary, the plan would be bulky and clumsy.

Now a very simple plan might be used, which is open to none of these objections, and has certain special advantages of its own. Let the coffin be made of some soft easily decaying wood, well joined together, and pitched inside. Let the lid be a framework of wood, filled in with thin glass painted black, or whatever colour be adopted, all except a portion which would correspond with the face of the deceased. When the body is placed in this coffin, let it be surrounded, all but the face, with carbolised tow, or with quicklime mixed with McDougall's disinfecting powder (if we desire a speedier process of decay), and covered at once by the lid. On the day of burial the face portion of the glass lid must be painted over, or covered by affixing a breast-plate, made of paper, linen, or leather, on which the name, age, and date of death are painted or embossed. On being deposited in the grave, which would be dug simply in the earth, the coffin would be thinly covered with quicklime and then by the earth. It is evident that the weight of the superincumbent soil would quickly break the glass lid, and permit dust to mingle with kindred dust.

The advantages of this plan peculiar to itself are:—1st. It would require no special manufacture, but could be carried out by our ordinary undertakers. 2nd. It would be cheap. 3rd. It would be safe to the survivors. 4th. It could be applied soon after death. 5th. The survivors could see with safety, and without smelling any odour, the face of the deceased up to the day of burial. 6th. The body could be kept a considerable length of time, especially if the coffin were made air-tight, and the air afterwards exhausted. 7th. As the process of decay in the grave would be very quick, the ground could be used very frequently for reburials, and, being in course of time well fertilised, would be well adapted for making Mr. Haden's beautiful garden, even though it were situated, as he proposes, in the Essex marshes.

I am, Sir, yours truly,
Colin Henderson.

Redcliffe-gardens, South Kensington, S.W.

ROYAL COLLEGE OF SURGEONS.

The result of the elections at the Royal College of Surgeons on Thursday last will give general satisfaction. There was a large attendance of fellows, and for a time the contest was spirited. As we ventured to predict, the three successful candidates were Mr. Prescott Hewett, at the head of the poll with 127 votes; Mr. Cooper Forster stood next, with 110; and Mr. Birkett third, with 109 votes. Mr. Spencer Smith, one of the retiring members, on whose behalf great efforts were made, polled only 97 votes, although a very large proportion were "plumpers." Mr. Alfred Smee gained 30 votes, and Mr. Hussey, of Oxford, 29.

BIRMINGHAM MEDICAL INSTITUTE.

Mr. Edwin Chesshire presents his compliments to the Editor of The Lancet, and begs to be permitted to announce through its columns that, in consequence of the admission of homœopathic practitioners to the Institute, he has thought it his duty to resign his connexion therewith; also to express his intention to withdraw his donation of £25, and give it to other and more deserving medical institutions. Mr. Chesshire will further be obliged by the publication of the following letter:—

"83, Newhall-street, Birmingham, June 28th, 1875.

"Dear Sir,—Would you oblige me by removing my name from the list of members of the Institute, though I deeply regret having to separate myself from a society in the prosperity of which I should have taken great interest, and in which amongst its members are to be found many of my warmest and best friends. The unfortunate course which has been adopted since the formation of the society constitutes, in my opinion, the most unwise, the most unjust, and the most illiberal act which has happened to the medical profession in the present generation.

"I am, dear Sir, yours very truly,
Edw. Chesshire, F.R.C.S.

"G. F. Evans, Esq., M.D., Hon. Sec.

"P.S.—I shall reserve to myself the privilege of sending a copy of this communication to the medical journals."

THE LANCET.

LONDON: SATURDAY, JULY 3, 1875.

In addition to the discussion by the Council of the Reports of the Visitors of Examinations, to which we have devoted another article, we have to notice a subject of considerable interest which occupied the attention of the Council on the two remaining days of its session—Friday and Saturday last.

The debate on the fitness of the medical profession for women was very creditable to the Medical Council. Our readers will have read for themselves the letter of Mr. Simon, written under the direction of the Lord President of the Council, and to be found at page 891 of The Lancet of June 26th. We can almost imagine Mr. Simon, earnest and scientific, and withal statesmanlike though he be, getting a little sense of—we must not say fun nor mischief—but some compound of these two sensations, out of the duty of composing this letter in the name of the Lord President. The Medical Council, as its name implies, is made up of the grave and reverend representatives of all that is regular and conservative in the constitution of the profession. They have known the profession only as it is—made up of male units who have gone through a certain well-prescribed course of study, observed certain "examination-rules and other conditions," and so passed into the great calling of which hitherto they have had the monopoly. Fancy the medical adviser of the Privy Council having, in the name of a Conservative Government, to propound to the Medical Council the general question—whether women ought to be able to look to medical practice, or certain branches of it, as open to them, equally with men, as a profession and means of livelihood, and in the name of His Grace to ask for the observations of the Council on this subject. Without pretending to divine Mr. Simon's sensations as he penned his letter, it is certain that no communication has caused such a sensation in the Medical Council, or produced such lively embarrassment, since the receipt of another celebrated letter from the same pen on the subject of Conjoint Boards in the year 1869. One would have thought that the views of the Medical Council on such a question might have been taken for granted, and that if any legislative action had to be taken in favour of women the Council might have been spared the delicate duty of either sanctioning or opposing it. But the Lord President seems to have thought otherwise, and considered that it would be a help to the Government to be in possession of the opinions of a body so technically and generally informed as the members of the Medical Council.

As we have said, the discussion of the subject and the answer to the Lord President are altogether creditable to the Council. Two or three replies to the Lord President's letter were open to the Council. One was to the effect that, sitting as mere administrators of an Act of Parliament, it was no part of their duties to give their views on questions not raised in the Act itself. Dr. Storrar proposed this reply, but was only supported in doing so by the seconder of his motion. Another reply was to the effect that women are totally unfit by nature for the stern duties of the medical profession, and that law ought to be consistent with such unfitness, as it is at present. This was the spirit of the manly and outspoken speech of Dr. Andrew Wood and of the reply which he proposed to send to the Lord President. But the Council took a different course, and we think one entirely consistent at once with its dignity and its opinions. The tenor of its answer will best be gathered from studying the following paragraph, first as it stood in the original report of the committee appointed to consider the matter, and then as it stood finally on the amendment of Dr. Parkes, who must be considered as the friend of the ladies on this important occasion:—

"The Medical Council are of opinion that the study and practice of Medicine and Surgery, instead of affording a field of exertion well fitted for women, do, on the contrary, present special difficulties, which cannot be safely disregarded."

Professor Turner fought well for this way of putting it. Dr. Parkes, on the other hand, as an amendment, proposed to end the paragraph by putting after the words "cannot be safely disregarded" the words "but the Council is not prepared to say that women ought to be excluded from the profession"; and he carried the amendment by a majority of 14 to 7. This amendment of Dr. Parkes expresses well the feeling of the majority of the Council on the whole question. It was voted for by the representatives—to take them nearly in the order in which the names occur in the division list—of the College of Surgeons of England, of the University of Oxford, of Cambridge, of Durham, of Glasgow, of the King and Queen's College of Physicians, of the College of Surgeons of Ireland, of the Apothecaries' Society of Ireland, and by five out of the six representatives of the Crown. Having made the admission that the Council is not prepared to say that women should be excluded, they go on to express the opinion that, if it should appear to the Government and the Legislature that women who wish it should not be debarred from obtaining a legal status as medical practitioners, it should be obtainable only under certain conditions and arrangements, which will be found specified in our report, and the principal of which most properly is that "in the interests of public order the education and examination of female students of medicine should be conducted entirely apart from those of male students."

The significance of this kind of reply from the Medical Council will probably be overrated by the eager ladies who are so anxious to distinguish themselves as medical practitioners, and by their political allies. To be rightly understood, it must be read in connexion with the speeches by which Dr. Parkes's amendment was supported, which certainly were the most telling speeches in the debate. If we might single out those which probably influenced the Council most, we would specify those of Dr. Rolleston and Dr. Humphry. Sir Dominic Corrigan did not vote, but he leaned to Dr. Parkes's amendment, while he said that, rather than see his daughter enter the profession, he would prefer to see her in her coffin. This is too strong, but in less extreme terms the same feeling was expressed. In other words, while the Council, realising its responsibility as a medical body having relations with the State, and actually consulted by Government, was unable to justify the legal exclusion of women, it made no secret of its opinion that the profession as a calling is most unfitted for them. The Council says that, so far from being well fitted for women, the study and practice of our profession present "special difficulties which cannot be safely disregarded." Not one of the speakers advised women to study medicine. And even Dr. Parkes assented to the view that medicine was a profession of special difficulties for them. Here the question must rest as far as the Council is concerned. If statesmen are to legislate for the admission of women, it will be on their own responsibility, and they will have to devise means of separate study for women, and to confess that, if they are to be admitted to the profession for which they are least fitted, they cannot be excluded from any other. Our opinion is not different from that of the Medical Council. We do not see it right or necessary to exclude women by law from a profession which physiology and common sense should teach them is meant for men, and is a hard calling even for these.

◆

In making a few observations on the Visitors' Reports of Examinations we would remark, that they promise to be of the greatest service in raising generally and equalising the standard of education throughout the country. In a few years we hope it will no longer be possible for a candidate who has been rejected for gross ignorance and incompetence at one board to disappear for a fortnight and return with the diploma of another. The General Medical Council has acted throughout in a thoroughly wise and lenient spirit. They have never exerted the power they undoubtedly possess of appealing to the Privy Council, by whom certain alterations might be directed to be made in the conduct of the examinations; but they have trusted to the steady and irresistible influence of public opinion, which will slowly, it may be, but surely lead to improvements. These improvements upon the old plan of examining are, first, that every examination should consist of three parts—a written, an oral, and a practical. It is not, of course, every subject that admits of such a division; but in the three examinations that are now held to be requisite for a degree or licence to practise, and which, by whatever names they are called, are equivalent to a preliminary, an intermediate, and a final examination, there are always subjects which can be thus treated. Thus, in the Preliminary Examination, Chemistry and Botany; in the Intermediate, Anatomy, and perhaps Physiology, and Materia Medica; and in the Final Examination, Medicine, Surgery, Midwifery, and Forensic Medicine,—may all be examined upon by written papers, by word of mouth, and by demanding some evidence of the acquirement by the candidate of that manipulative dexterity which is of the highest importance in practice, and which cannot be got from books, but requires attendance and work in the laboratory, the dissecting room, and the wards. No examination can be held complete from henceforth which neglects these three methods of examination. They have already been adopted by the best and most advanced of our examining bodies, and those who neglect them in the future will be thrown out of the race altogether, and their diplomas, if taken at all, will possess a very inferior value. Difficulties there may and must be in carrying out some of the necessary arrangements of these subjects, especially when the number of candidates is considerable, and this is notably the case in the performance of dissections; but we are persuaded that these could be overcome by a little exertion and forethought on the part of the examining bodies. The improved methods of preserving subjects enable them to be retained for several weeks, or even months; and with economy and care many candidates could be examined on two or three subjects even though some dissection were required from each.

For the written examination fair time should be allowed to the student—three hours at least on every subject; and in the more important ones—Anatomy, Physiology, Medicine, Surgery, and the like—six hours cannot be regarded as too much. The oral examination must be left to the discretion of the examiners. A good man may be dismissed in five minutes; a doubtful one may require half an hour before his passing or rejection can be decided upon.

In the next place, two examiners should be appointed at each examination on every subject, each having the power to pass, but not to reject without conference. Thus, whilst responsibility is shared, the student has a guarantee that he has not been rejected from any personal peculiarity on the part of his examiner. With this duplication of examiners we would gladly see conjoined the plan so strongly and consistently advocated by Professor Humphry, of the introduction of a foreign element into the constitution of the examining board of every university or college, so that the candidates should not be examined by their teachers and lecturers exclusively. Need we add that the foreign element should be the best that can be obtained for love or money?

A perusal of a considerable number of the examination questions given in these reports suggests some curious reflections; for whilst some bear evident marks of careful consideration, others give the impression that the writers have not clearly distinguished between Anatomy, Physiology, and Histology.

One point more. Since students cannot be expected to be experts in a score of different subjects, would it not be well that in the regulations for examination the amount required should be restricted, but clearly laid down and rigorously exacted?

◆

We beg to direct particular attention to an important article which we publish this week respecting an inquiry by Sir Henry Thompson into the condition of fifty-one cases of lithotrity in elderly adults, made at periods of from one to two years after the operation. It will be remembered that in our columns for April 3rd Sir Henry published a brief record of 100 cases of stone in the bladder, 96 being in males and 4 in females. Of the 96 males, 87 were operated on by lithotrity and 9 by lateral lithotomy. The mean age of the 87 operated on by lithotrity was sixty-three years and a half, and the mean age of the 9 operated on by lithotomy was also sixty-three years and a half. Of the former 4 died, and of the latter 2 died. There were therefore, in the two operations, 6 deaths in 96 cases, or 1 in 16. The result as concerned the lithotrity cases was very satisfactory, the deaths being only about 1 in 22. Mr. Thomas Smith, however, suggested an important question—namely, the relative condition of patients on whom lithotrity had been performed at any period not less than twelve months after the operation. Sir Henry Thompson has now published his answer. With great care and trouble, he has ascertained, by personal examination, or by the reports of the various medical attendants, the condition of the patients at a period varying from two years and a half to thirteen months after the operation. Within the prescribed period lithotrity was performed on 53 persons, of whom 2 died. For the full details the reader must turn to Sir Henry Thompson's own statements. Suffice it to say that of 45 cases 11 have died and 34 are still living, of whom 28 enjoy good health and active existence, at a mean age of sixty-three years and a half (6 have been lost sight of); 6 have shown signs of recurring calculus, 2 having had newly formed calculi removed; of these all are well but one. But even these figures do not fully represent the relative advantages of lithotrity, for, as Sir Henry suggests, there are many instances in which recurrent phosphatic accumulations are readily removed again and again by the lithotrite. Persons so afflicted really owe their lives solely to surgical art, and, except for lithotrity, must soon perish, or frequently submit themselves to the more hazardous operative procedure of lithotomy. In the interests of surgery and of humanity this investigation is of inestimable value, and too great praise cannot be awarded to Mr. Thomas Smith for his pertinent suggestion, and to Sir Henry Thompson for the able and careful manner in which he has met it.

◆

A Royal Commission has been appointed to inquire into the practice of subjecting live animals to experiments for scientific purposes, and to consider and report what measures, if any, it may be desirable to take in respect of any such practice. The Commission is composed of Lord Cardwell, Lord Winmarleigh, Mr. Forster, Sir John Karslake, Mr. Erichsen, Prof. Huxley, and Mr. Hutton; and those who, like ourselves, desire to see the subject calmly and dispassionately considered from all points of view will regard these names as a guarantee that such will be done.

The statements that appeared from time to time regarding some of the real or alleged practices on the Continent under the name of vivisection excited a good deal of indignation, and raised a feeling of unnecessary alarm lest a similar wholesale system of animal experimentation should be pursued at home in the supposed interests of science. We entertained doubts as to the accuracy of the alleged statements of what was done abroad, but, whether these were true or false, we never had any doubt that they afforded no fair indication of what was done, or likely to be done, in this country. It appeared to us that many very exaggerated assertions had been made, and that a good deal of irrelevant matter had been introduced into the discussion on both sides. Because power over the lower animals has been given to man, that is no reason why he should arrogate to himself the right to use it regardless of the suffering he causes or a sense of the responsibility he incurs. Still we have never entertained a doubt that experiments on animals are perfectly justifiable within certain limits and under certain circumstances, and we wanted to know, if possible, what these limits and circumstances were, in order that any necessary restraint should be imposed. But it was, first of all, essential to ascertain something as to the extent and prevalence of vivisection in this country. It seemed to us that all attempts at legislation would be futile and like leaps in the dark without some more precise information than is at present available. We strongly urged the importance of appointing a Commission as a preliminary step. With the composition of that Commission we think the public has every reason to be satisfied. Those whose minds have been strongly made up one way or the other will, of course, be dissatisfied with a Commission which promises that the matter will be divested of false issues, and quietly and impartially deliberated upon. Lord Cardwell has the reputation of possessing a judicial tone of mind, and he has had the benefit of a legal training. Mr. Forster is an eminently fair and broad-minded man. Mr. Hutton has a keen, logical intellect and a lively sensibility; his constitutional dislike to the infliction of pain of any kind has probably led him to take an active part on one side, and he can scarcely fail to become more fully instructed in the subject by understanding the views of men like Professor Huxley and Mr. Erichsen, with whom he is associated in this inquiry. We claim to have approached the matter ourselves in a dispassionate spirit, and with the sole desire of getting all the light that can be thrown on a difficult subject before anything in the way of legislation be undertaken in regard to it; and we believe that the Government has adopted the wisest and best, if not the only practicable, course in appointing this Royal Commission.

Annotations.

"Ne quid nimis."

THE COUNCIL AND THE CONJOINT SCHEMES.

The representative of the College of Physicians, Dr. Risdon Bennett, put a question to the President of the Medical Council as to the present position of the Conjoint Scheme for England. Dr. Apjohn also asked Mr. Macnamara, as the representative of the Irish College of Surgeons, whether the Council of the College still adheres to the scheme agreed to by the other Irish bodies and sanctioned by the Medical Council. Dr. Acland's answer was studied, and if not sanguine, yet not desponding. He had no reason to believe that the College of Surgeons had withdrawn from the scheme. There was a little ambiguity in his words about the action of the College. "It had always maintained or implied the right to secure the nomination of a certain proportion of the examiners in surgery and anatomy. If the right be *now* insisted on, the consent of the other bodies and of the Medical Council is obviously necessary. These circumstances show that the negotiation is one which in its nature requires time, but they do not indicate that the scheme will come to an end." If the College is only asking for what it has always asked, seeing that the scheme is now two or three years old, it is rather curious to hear that "time" is still wanted. Mr. Macnamara says that the Council of his College is still pledged to the scheme approved by the

Council, "but during the past year the question has fallen into abeyance. The present feeling in Ireland is that we should be very much influenced by the steps which may be taken in England and Scotland in this direction." And so this great matter remains "in abeyance," the subject of a mere chance question at the tail end of the session of the Council, Ireland waiting to see what England and Scotland will do, and nothing decisive being done in the matter. We confess to being less sanguine than Dr. Acland. But *nous verrons.* Sir John Lubbock's Bill will soon be law, and we shall learn whether the ingenuity of obstructiveness is yet exhausted.

OPIUM TRAFFIC.

IN the debate on the Indian opium monopoly on the 25th ult. there was much difference of statement as to the consequence to the system of the habitual consumption of the drug. That its ultimate effects are most serious there is no doubt. The temporary endurance and strength which it supplies afford no ground (as some speakers imagined) for denying its injurious influence. Even in moderation its effects on the system are very enervating, and, as with all other stimulants, moderation seems to be impossible to a large number of those who indulge in the use of the drug. The opium-eater soon becomes absolutely dependent upon it for whatever capacity he possesses of work or enjoyment, a capacity which soon it is beyond the power even of opium to preserve. Moreover, the sketch of the peasant and his innocent after-dinner pipe of opium is very fallacious. Those who have seen much of Eastern natives, in country districts as well as in towns, affirm that it is very rare for opium to be taken in one form only. The opium-smoker is almost always the opium-eater also. Nor is the argument for the use of opium which has been drawn from the consumption of alcohol in this country of greater point. Opium as a stimulant may be better or worse than alcohol, but the ultimate effects of even a slight habitual excess of alcohol are sufficiently grave. No argument, then, drawn from the innocuity of opium can excuse the Government of India for the prominent position it occupies as, practically, the great producer of the drug. It is much to be regretted that the financial prosperity of India should be dependent, as it seems to be, on the amount of drunkenness in China. It is still more to be regretted that the Government occupies so invidious a position as the farmers of the whole opium cultivation of Bengal. Against a transfer of the mode of raising the revenue from the cultivation to the taxation of opium, from production to prohibition, the uncertainty and fall of revenue seems the only real objection, and it may be hoped that prosperous seasons and a wise government may soon render the objection trivial, and that the means may be found to abolish what has long been felt to be a grave injustice.

EUCALYPTUS GLOBULUS.

OUR readers are aware that the result of extensive administration of the Eucalyptus globulus in intermittent fever has hardly corroborated the promise of early and more limited experience. It appears to have very little power of arresting the frequency of the attacks, or of warding off the grave organic consequences of the disease. But it is interesting to find that its alleged influence on malaria has received some substantial confirmation. Dr. Cosson recently announced that its effect in Algeria had been very marked. Since the growth of plantations of this tree around the lake of Fezzara, the malaria which formerly was intense has almost disappeared.

The village of Ain Mokra, according to Captain Ney, furnishes an equally striking instance. The station was formerly so unhealthy that it was necessary to change the French garrison every five days on account of the number of men attacked. Fever has, however, become much more rare since plantations of Eucalyptus globulus have been made on the shores of the lake and the sides of the railway, which include altogether 60,000 trees. A writer in the *Temps* mentions a still more singular effect—namely, that parasites (phylloxera, &c.) disappear from vines growing near the eucalyptus. The experiment, made during several years and in several vineyards, had been uniform in its result.

It is interesting, in connexion with these facts, to observe that the leaves of this plant contain an ethereal oil, of which even half-dried leaves contain 6 per cent., and that this oil, according to Gimbert, is a very powerful antiseptic. It will preserve blood and pus as long as carbolic acid (five months and more), and far longer than oil of turpentine. It prevents also the appearance of fungi or vibrios. These observations have received independent confirmation from Binz, in Germany.

DR. GUY'S HARVEIAN ORATION.

IN the Harveian Oration, delivered at the College of Physicians, Dr. Guy did not depart from the tradition which assigns to the life-work of Harvey the paramount place in the thoughts and words of the orator. Previous orations have, as Dr. Guy observed, either been devoted to Harvey and his labours, or else to some topic connected with modern discovery and research having more or less close relation to the subjects which occupied Harvey's fruitful intellect. The great discovery of the circulation of the blood was the somewhat trite theme which Dr. Guy selected. He contrived to invest it with some new interest from the aspect in which he considered it—that of the personal character of Harvey's work. Great as were the obstacles Harvey had to encounter, all was not against him. The conditions of his own life, of his own education, were all favourable. He came of a wealthy family, and had independent means of his own, so that he could command the very best education which England or Italy could give, besides which he was able to obtain by royal favour or otherwise access to other sources of study beyond the general reach. It was an age of some vigorous thought, and Harvey was in close contact with whatever of intellectual activity was going on in Europe. His great characteristic, that of careful sceptical observation, freed him in great measure from the trammels of previous theory, which, more than anything else, hinders the discovery of truth. But Harvey's discoveries were far more than mere instances of happy and acute observation. They were careful inductions of remarkable sagacity and of the highest order of logical thought. They were also of very varied character. In no one, perhaps, does the part played by imagination in scientific discovery appear with such signal power and effect. It appears in every line of the history of his discoveries, and is seen, as Dr. Guy pointed out, in his tendency to personify the objects of his investigation, until sometimes his solid footing seems to fail him, and vague mysticism obscures the clear light of his intellect, and leads him on to a too ready credulity where his own individual observation could not penetrate. A curious instance of this is Harvey's belief, alluded to by Robert Boyle, that certain tumours might be dispersed by the touch of a dead man's hand. The cobwebs of hypothetical explanation, which his own mind swept lightly from the facts beneath, still obtained in the eyes of his contemporaries, and hindered the reception of his discoveries, as in all ages they have hindered knowledge and embarrassed the discoverer. Much of his time had to be spent in detailed discussion and disproof of the erroneous views which were generally held on the points to which his discoveries referred. The versatility of Harvey's mind was as remarkable as the extent of his researches and the minuteness of his investigations. The subjects on which he had thought and intended to write comprehend a large part of physiological science, and his thoughts ranged over a still wider area, and found relaxation in mathematical and classical pursuits.

Harvey united in singular completeness the practical and scientific elements of character which are alike indispensable to the highest order of intellect. A large share of his success as a discoverer is due to the ingenuity with which he devised and executed his experiments; and his own writings show how readily he utilised in actual practice his own great discoveries. Of the originality of those discoveries, Harvey himself, as Dr. Guy clearly showed, entertained not the smallest question.

THE PUBLIC HEALTH BILL.

The Public Health Bill would appear to be about to pass through the House of Lords with as little difficulty as it passed through the House of Commons. The Duke of Richmond, in moving the second reading of the Bill, gave a clear statement of the present position of sanitary legislation and of the advantages to be gained in future legislation by a consolidation of existing law. With reference to the few amendments proposed to be introduced other than those which the Bill had received in the House of Commons, he said that, under existing provisions, "the local authority had the control of sewers as well without as within their district, and were empowered to carry water mains beyond their district underground. This power did exist at present in regard to sewage, and it seemed only reasonable that it should exist in regard to water, which was equally necessary to the health of the community. Further, the waterworks clauses were incorporated in the Bill in accordance with the recommendations of the Select Committee. Another clause increased the limit of the cost of the water-supply to twopence per week. Then power was granted to local authorities to suppress trade nuisances; to urban authorities to purchase or provide gasworks by agreement; to sanitary authorities generally to proceed against joint contributors to a nuisance; and to the Local Government Board to unite districts and appoint medical officers of health. The provision as to joint contributors to nuisances was framed because it was sometimes difficult to distinguish who the offending party really was." The Duke of Somerset took exception to the Bill generally because it was what it professed to be and not something else; the Marquis of Salisbury, Lord Aberdare, Lord Redesdale, and Earl Fortescue supported the Bill. Lord Aberdare intimated his intention of moving an amendment for strengthening the hands of the Local Government Board in dealing with local authorities who failed to do their duty. The Bill was read a second time.

NORTH OF SCOTLAND MEDICAL ASSOCIATION.

On the 26th of June the annual meeting of the North of Scotland Medical Association was held at Aberdeen, and was attended by a fair muster both of town and country members. The proceedings were opened by an excellent address from the president, Dr. R. Jamieson, superintendent of the Royal Lunatic Asylum, who, in the course of a review of the progress and improvement in the treatment of the insane, took occasion to advert to the great increase of insanity in Scotland — an increase not only absolute but relative, as shown by the great extension of lunatic asylums and the lunatic wards of poorhouses, and to such an extent that the last Census shows the ratio to be 1 in every 430 of the population—a ratio which seems steadily on the increase. This increase Dr. Jamieson is inclined to attribute to an artificial system of living, to the race after wealth which more or less characterises all classes of the community, and to the excessive system of cramming and urging the brain to overwork which marks the present plan of education in the young, more especially in children. The great experience which Dr. Jamieson has had in the treatment of the insane gives force and value to his opinion on such a subject, and is well calculated to make us pause and think whether our high-pressure civilisation is really worth the cost it entails, or whether the loss in health to the community may not counterbalance the advantages obtained in other ways.

The Association then took up the question of a proposed Scottish Medical Association—a scheme which has been mooted by some of the medical societies in the south of Scotland, but which has not yet assumed a tangible form. The Association, without committing itself definitely to the proposal, agreed to appoint a committee to confer with the proposers of the new Association, and report.

The question of a code of ethics, which has been in one form or another before the Association for some two years, was then taken up; but the discussion did not result in any definite action being taken.

SUCCESSFUL REMOVAL OF THE LARYNX.

Our readers have not forgotten that Professor Billroth, of Vienna, performed this operation, and that the patient died several months afterwards. Professor Bottini, of Novara, (*Gaz. Med. di Torino*, No. 10, 1875) has just followed his example. The patient is a healthy young man, who, on account of dyspnœa, had already had laryngotomy and galvanic cauterisation of the larynx performed. The operation lasted ninety minutes, and left the patient much exhausted. He was, however, revived by injection of beef-tea and wine. It was found that the larynx was quite obstructed by a greyish-red tumour. In spite of an attack of erysipelas and a series of abscesses, the man gradually improved, regained the power of deglutition, and was able to cough, breathe, and sleep well. The wound has healed up, and the case, save future accidents, may be looked upon as successful.

SANITARY DIFFICULTIES AT LEEDS.

An influential deputation recently waited upon the Marquis of Salisbury, in order to point out the difficulties that would exist at Leeds in carrying out the provisions of the Rivers Pollution Bill, if this Bill, now before Parliament, became law. Leeds, as everyone knows, contains a number of dyeing and other factories, that require for their daily use about 50,000 tons of water. When this water has been utilised, and thus polluted, it is discharged into the river Aire, whence a large proportion of it had come. The Act above-mentioned will of course prevent any such discharge into the river, and so the manufacturers say, What shall we do with it? For if the refuse water be discharged into the sewers, the river will be deprived of its proper volume, and so injure those interested whose works are situated below the town of Leeds. It may be mentioned that the authorities are now endeavouring to purify their sewage by the A. B. C. process, which, though not remunerative, produces a sufficiently good effluent water to satisfy the terms of the Chancery injunction, under which the town is now prevented from discharging its sewage into the Aire. Practically speaking, the refuse water from all factories except tinplate and galvanising works and wire-drawing, can, according to the testimony of Dr. Frankland (given before the House of Lords in 1873), be treated at the outfall with the sewage, and in order to neutralise the objections stated above, it is proposed to pump the effluent water from the sewage works back to the town, which can be done at a smaller cost than that charged by the authorities for their own water-supply, the effluent water being quite fit for all manufacturing purposes. The products of the sewage are not likely to be valuable, for though Leeds has a population of 259,212 inhabitants, and 55,827 inhabited houses, it possesses no less than 13,500 middensteads of the old type, which, according to Mr. Netten Radcliffe, are perpetuated by the building laws of the corporation, some of these gulfs being so vast that an individual falling accidentally into them might readily lose his life. We quote this latter fact to indicate that neglect on this head intensifies the difficulty under which the corporation is likely to labour in dealing with the provisions of the forthcoming Act.

HYDATID CYST IN THE PONS VAROLII.

ABSOLUTELY sudden death from encephalic disease is most rare, but occurred in a case recorded by Dr. Fredet, of Royat. A hydatid cyst, occupying the upper portion of the pons Varolii on the right side, ruptured, and the sufferer, a young man, aged twenty-two, who was at the time walking along the road, fell to the right, and was found to be dead. Some spasm of muscles on the right side of the face and jerking of the head to the right were noticed just before he fell. Headache and neuralgia of the right fifth nerve had been complained of for some months. A few cases only are on record in which a similar sudden termination has occurred in cerebral hydatid disease. One was recorded by Blin in which a woman of twenty-three died suddenly in consequence of a hydatid cyst in the left lobe of the cerebellum; and in another case, given by Davaine, a man died suddenly in consequence of a similar cyst in the right posterior cerebral lobe. The seat of the disease in Dr. Ferdet's case—not far from the respiratory centre—renders the instantaneous death more easily understood than in the other cases.

MEASLES IN FIJI.

A CORRESPONDENT of *The Times*, writing from Levuka, the principal village in Fiji, gives an account of the importation of measles into the island, and graphically describes the terrible fatality caused by the disease. So far from the disorder having been communicated in the first instance by English seamen, it appears that the King and his party, when on the now memorable visit to Australia, were all attacked with measles of a mild type during their stay in Sydney, and were only convalescent when they returned home. The disease soon declared itself in a most malignant form, and carried off nearly all the Fijian chiefs. In spite of the unremitting efforts of the Government medical officer and of the small body of European colonists to arrest the progress of the epidemic, it ran rapidly through the whole island, necessitating the conversion of every public building into a hospital. One locality is said to have resembled a vast charnel house. Altogether it is said that 20,000 of the natives have died, and this computation is probably very near the mark. There is reason to hope that the disease has now exhausted itself. A medical account of the epidemic, which we have no doubt will be forthcoming in due time, cannot fail to be interesting and instructive. There are many points capable of being worked out—e.g., it has been stated that the disease declared itself in different parts of the island within a week of the arrival of the royal party. Now the usual incubative period of measles in this country is fourteen days—very rarely less than twelve, although inoculated measles has an incubative period of seven days. Its rapid extension is in accordance with the experience of outbreaks of measles at home. The material prosperity of Fiji—although it has received a temporary check—after so recent an emancipation from barbarism, justifies a belief that there is a bright future before the little colony.

SUMMER DIARRHŒA IN TOWNS.

NOTWITHSTANDING the moderate, not to say low, temperature which prevailed from 10th June until the end of the month, the last Weekly Return of the Registrar-General showed a marked increase in the fatality of diarrhœa in 18 of the largest English towns. During the week ending 26th June, 140 deaths were referred to this disease in the 18 towns, against 75 and 104 in the two preceding weeks. In the corresponding week of the three years 1872–3–4 the deaths from this cause in the 18 towns were 50, 59, and 123 respectively. The 140 deaths in the 25th week of this year included 77 in London, and 63 in the 17 provincial towns; the annual rate of mortality in the week from this cause, which averaged 1·1 per 1000 in the 18 towns, was 1·2 in London, whereas in Hull it was equal to 3·1 per 1000. The 77 fatal cases in London included 56 of infants under one year of age, 15 of children and young persons aged over one year and under 20, and 6 of persons aged more than 40 years. The rate of mortality from diarrhœa in the week under notice was considerably lower in South London than in other parts of the metropolis. In the "outer ring" only one death was referred to diarrhœa, whereas in East London, with about the same population, 18 fatal cases were returned. Summer diarrhœa among infants is almost exclusively an urban complaint.

ABDOMINAL CYSTIC FIBROMA.

AN unusual variety of abdominal tumour was recently removed by Mr. Spencer Wells, and forwarded to Virchow, who described it in the last number of his *Archiv*. It was situated behind the peritoneum, the exact attachment being unknown, but both ovaries and uterus were healthy. It contained a large cyst, the size of a head, filled with pus. The walls consisted of fibrous tissue, delicate and soft, dotted with spindle-shaped and stellate cells; while in the intermediate tissue, between the fibrous bundles, were large round degenerating cells. The structure of the vessels was curious. The walls of both capillaries and small veins presented, when acted on by acetic acid, a distinct cellular structure, clear large nuclei being scattered over the whole field enclosed in elongated areas. The tumour is classed by Virchow among the varieties of fibroma molluscum which occur in the sexual apparatus, and he compares the formation of a cyst, and its subsequent inflammation, to the changes in similar subcutaneous tumours.

LIERNUR'S SYSTEM OF DRAINAGE.

WE have received information that on the 3rd of May the Emperor of Russia signed a contract for the introduction of the Liernur system of drainage into St. Petersburg. It is first to be laid in one district containing 15,000 people, and then, if successful, to be extended to the whole town, which contains 600,000 inhabitants. The report of the Russian engineers has been very favourable, and they have estimated the cost of laying down the Liernur triple system at less than that required to put down ordinary sewers on the water-flushing principle. We have often spoken favourably of Captain Liernur's method of sewage removal, and are now glad to see it has a chance of being practically tried on a large scale. If successful it will solve the problem of sewage disposal most completely, for, on theoretical grounds, there is no doubt the principle is a right one. We think it a great pity the scheme has not been tried in England. The reports of the Dutch and Russian engineers have been eminently satisfactory, as is shown by the adoption of the system in Amsterdam, Leyden, and St. Petersburg; and we think if the sanitary authorities of these countries have consented to give the scheme a fair trial, we ought to be public-spirited enough to make an effort in the same direction. If a district were selected in some large town that is difficult to drain under the present system, and the Liernur method tried experimentally, the cost involved would not be much, whilst the practical results of the working would be speedily ascertained. At all events, Government ought to give us a full and complete report as to the success attending the working of the system in the foreign towns in which it is already carried out. We have no wish to force this or any scheme on sanitary authorities, but we think more attention ought to be paid to Captain Liernur's method than has hitherto been the case, since it has been stamped with the approval of foreign sanitary engineers.

THE WORCESTER INFIRMARY.

Dr. Inglis has very properly resigned his appointment as Honorary Physician to the Worcester Infirmary, in consequence of the Executive Committee having passed what he regards as a vote of censure on him for leaving his infirmary out-patients to be seen one day by the house-surgeon. The Committee says it was his duty to have got another member of the honorary staff to do the work. The Committee must have strange ideas as to the life of a physician, and what consideration is due to honorary officers, especially those of such standing as Dr. Inglis, and of his length of service. If the Committee adheres to the position he should adhere to his resignation. But we venture to believe that the body of governors will show that they have a greater sense of propriety, not to say gratitude, than the Executive Committee. The point in dispute is one of interest to the whole staff, and Dr. Inglis should not be left to fight alone.

DISCUSSION ON PUERPERAL FEVER.

We understand that the debate at the Obstetrical Society will be closed on Wednesday next, when the last meeting of the Society before the recess will take place. Professor Fordyce Barker, of New York, is in London, and will take part in the discussion. As Dr. Barker is known to hold views opposed to those expressed by most of the gentlemen who have already spoken, and as Mr. Spencer Wells will reply to the observations made upon his paper, the meeting promises to be both interesting and spirited.

Among the specimens to be exhibited at the beginning of the meeting is, we believe, one of singular interest by Dr. Newman, of Stamford, who hopes to be able to show the uterus of a woman on whom he successfully performed Cæsarean section nine years ago.

CEREBRAL PHYSIOLOGY.

M. Lepine recently communicated to the Société de Biologie some experiments on the effect of the faradisation of the convolutions on arterial tension. The observations were made on dogs which had been placed under the influence of curara. It was found that the stimulation, by a weak current, of the pre-frontal or of the post-frontal convolution produced a considerable increase of arterial tension. The phenomenon did not occur immediately, only after a "certain time." The increase of tension was accompanied by a sensible elevation of temperature in the paw on the opposite side. The effect on the heart varied according to the strength of the current. A weak current applied to these convolutions increased the rapidity of the heart's action; a strong current rendered it much slower. M. Lepine endeavoured to ascertain whether structural continuity of the nerve-fibres was necessary for the production of the effect, but in slicing off a portion of the cortex, the mechanical excitation of the nerve-fibres, in their division, produced the same effect on the arterial tension as electrical stimulation, and thus the experiment was prevented.

THE SOLDIERS' HUTS AT WOOLWICH.

It is announced that the huts on Woolwich Common, which had obtained such an unenviable notoriety in connexion with the late outbreak of diphtheria among the families of the married soldiers quartered there, are to be altogether swept away, and their site to be occupied by six blocks of model houses on the plan of the Cambridge cottages. The disease for which the families vacated the old cottages on the Common was a long time before it disappeared, the last case of diphtheria having, we believe, only been discharged from hospital towards the end of last month.

The Manchester and Salford Sanitary Association, in a report of its operations during the past year, complains that great difficulty was experienced in obtaining reliable statistics regarding the effect of noxious vapours on human life. Steps are being taken now, however, to secure the cooperation of medical officers of health in districts most subject to such vapours, and the Association hope soon to get important results of practical value to medical men and sanitarians. The law relating to smoke nuisances would appear to be extensively infringed in Manchester. We are sorry to find that this Association is suffering from want of funds. Its usefulness is unquestionable, and we therefore hope that the appeal which the Committee are compelled to make for support will be successful, and so enable it to enlarge its sphere of work.

The annual report of the Coppice, Nottingham, of which Dr. W. B. Tate is the Medical Superintendent, has just been issued. The Commissioners in Lunacy, on the occasion of their visit to the institution, were impressed with the great cleanliness, good order, and general air of comfort prevailing. Dr. Tate again urges the necessity of extending the usefulness of the charity by enlarging the building, the accommodation at present available being occasionally found quite insufficient. As his recommendation is supported by the Commissioners, we have no doubt that an additional wing will ere long be provided. At the Coppice lunatic patients are received who, not being paupers, are unable to pay the whole expense of their care and maintenance.

We are glad to learn that by command of Her Majesty the Queen a considerable quantity of cast-off linen suited for surgical purposes has been sent from Buckingham Palace for the use of the patients of the London Hospital. We hope a few of the other hospitals may participate in such benefits, and that the example shown by Her Majesty will be followed generally by heads of families. There would be no difficulty in supplying our hospitals with ample material of a sort available for the work of the surgeons and dressers, provided a scheme could be organised by a few influential ladies.

In London 1413 deaths were registered last week, including 2 from small-pox, 25 from measles, 62 from scarlet fever, 12 from diphtheria, 62 from whooping-cough, 27 from different forms of fever, and 77 from diarrhœa. Considering the low temperature prevailing during the period the mortality from diarrhœa seems to have been excessive. Different forms of violence caused 57 deaths.

THE Medical Officer of Health for Croydon, Dr. C. W. Philpot, as the result of his investigation into the outbreak of enteric fever in the district in March last, has obtained conclusive evidence to show that the epidemic was due to the pollution of the water in the mains, and also that this pollution was caused by an intermission of the water-supply. The disease was confined to an area supplied with water from the Croydon waterworks. We gather from Dr. Philpot's report that there is need of reform in the structural and sanitary arrangements of numerous houses in Croydon.

SMALL-POX has been prevalent in Darlington for some time past. At present there are about 35 cases of the disease in the town, the greater part of the patients being convalescent. Of these 20 had been treated in the Fever Hospital, to which fact may probably be ascribed the small mortality from the disease. The town authorities have been active in enforcing measures calculated to arrest the progress of the epidemic, and to confine it within its present quarters. It is stated that small-pox was brought to Darlington in January last by a pedlar who was journeying from town to town.

THE Dutch troops in Acheen, Sumatra, have been severely tried during the last three years or so. In addition to the perils from military operations against probably the most courageous of Asiatic peoples, they found great difficulty in securing sufficient provisions, and suffered from a want of good water. Cholera broke out among them, and caused a large mortality. Now, however, according to the latest reports, cholera has almost disappeared, the soldiers are in good health, and supplied with abundance of pure water obtained from artesian wells.

A DEPUTATION, composed of delegates from the South-East of London, Northumberland and Durham, and Lancashire and Cheshire Sanitary Associations, waited upon the Duke of Richmond on the 1st inst., to urge the insertion in the Public Health Bill of clauses enabling neighbouring authorities to take action in the case of noxious trades occurring outside their own districts. The Lord President promised to give the subject his earnest consideration.

THE fine model of a statue of the late Sir J. Y. Simpson, intended to be erected in Prince's-street Gardens, Edinburgh, was accidentally destroyed on the 26th ult. The model, which was the work of Mr. W. Brodie, was being shipped at Leith for London, where it was to be produced in bronze, when it unfortunately fell, and was shattered to pieces.

AN examination of candidates for appointments in the Indian Medical Service will be held in London on the 9th August next and following days. Copies of the regulations, together with information regarding pay and retiring allowance, may be obtained on application to the Military Department, India Office.

ACCORDING to the usual custom, the specimens added to the Museum of the Royal College of Surgeons during the past twelve months are now collected and exhibited in the theatre of the College, where they will remain until Thursday, the 8th of July.

THE great increase in the number of pauper lunatics in Surrey has caused the magistrates of the county to decide on the erection of a new asylum large enough to accommodate 1000 patients.

THE latest returns of contributions to the Hospital Sunday Fund give a total sum of £25,000. It is expected that at least one thousand pounds more will be received.

REPORTS OF THE VISITORS OF EXAMINATIONS IN 1874.

(*Concluded from vol. i., page* 898.)

The First Examination for the Degree of M.B. at Oxford.—The report of the Visitors in regard to this examination is a favourable one, the only point on which they comment being the advisability of introducing dissections. To this no objection can be raised beyond the difficulty of obtaining a supply of subjects. An excellent feature of this examination is that no candidate is allowed to present himself who has not passed all the examinations requisite for the B.A. degree.

The Examination for the Degree of M.B. University of Oxford.—This also met with approval on the part of the Visitors, who state that it was full, searching, and painstaking, the range of questions comprehensive, and the general scope of inquiry well directed, especially as regards the practical bearing of the questions in all the subjects.

The Examinations for the Degree of M.B. University of Cambridge.—The three examinations for this degree, the details of which are minutely given by the Visitors, show that a considerable amount of work is required in order that a candidate should be successful; and it is stated that the standard is well calculated to sustain the reputation of the degree, and to secure that those who possess it are fitted to promote the welfare of the community. It is very satisfactory to find that the impression produced on the minds of the two sets of Visitors who report on the examinations for the M.B. degree at our two chief Universities is so favourable, and that so little room is afforded for comment or fault-finding.

The First Professional Examination of the University of Durham.—On the occasion when this was visited only two candidates presented themselves; and the Visitors consider that it was difficult to arrive at a correct judgment of the value of the examination, especially as both the candidates failed to pass. The estimate of the value of the answers they consider was too high; and they recommend the appointment of two examiners in chemistry, which would enable a more definite and weighty opinion in regard to the merits of the candidate to be arrived at. The examiners are, in this University, the teachers; and there seems to be a plan, which cannot be regarded as advantageous, of allowing a candidate who has done well in several subjects to pass in these though he may have failed in another, and he may present himself for examination in the course of a few weeks in the subject on which he has been rejected. The Visitors refer this point to the consideration of the Council; but we imagine it can only meet with deprecation.

The University of Aberdeen.—On the whole this appears to be one of the best examinations in the three kingdoms. The arrangements of the examination are good, and the order of study excellent. One point strikes us as curious and impracticable elsewhere than in the far North. "The clinical examinations are held," it is said, "at the Royal Infirmary, and are extended over a period of *some weeks*, in order that recently admitted cases may be presented, to secure, as far as possible, that they have not previously been seen by the candidates." A feature of the examination which might occasionally be introduced into those of other examining bodies is, that an examination in practical pharmacy is held, when the competence of the candidates to prepare and dispense various medicinal compounds is tested. The Visitors strongly insist on the advisability of some of the examiners being chosen from without.

The First and Second Professional Examinations of the University of Edinburgh.—The University has, it appears, this year adopted the plan of selecting special examiners in the several subjects, eleven of whom had no connexion with the University. The comments of the visitors are entirely favourable. Students, it is remarked, are not admitted to the Second Professional Examination till after the completion of their third year of study; and as there is no elementary examination on anatomy their knowledge of the whole subject must be kept up till a late period of their career.

The Medical Examinations at the University of St. Andrews.—This University has the privilege of granting its degrees, not only to those who have passed through the curriculum of education and examination prescribed by the University, but also to ten registered practitioners annually above the age of forty, whose professional position and experience are such as in the estimation of the University to entitle them to that degree, and who, on examination, satisfy the medical examiners appointed by the University of their professional knowledge. The Visitors do not give a favourable report of the examinations in this University. A regulation is in force, enjoined by the Universities Commission, that every candidate should have spent two of the four years of his study at one of the British or Irish universities or colleges, and, as a result, only one or two candidates present themselves per annum. The examination fails, in the Visitors' opinion, to come up to the requirements of a modern pass examination. In regard to the granting the M.D. annually, after about an hour and a half's examination, the Visitors think the manner in which the privilege is exercised is unsatisfactory. The practitioners desiring it send in applications accompanied by testimonials, and ten are selected. If any fail, those next in rotation are selected. The Visitors do not think that the conferring of the highest degree in medicine, in consequence of the candidates having presented testimonials and passed such an examination as they witnessed, can be fraught with any real benefit to the profession or the public, or even to those who seek and obtain the degree. The stimulus is insufficient, they think, to induce the candidates to take pains in making preparation or to maintain that higher culture which such a degree should indicate. And this, they go on to say, is the more to be regretted because a very beneficial influence might be exerted by a judicious mode of exercising this privilege, and giving to practitioners who really merit the distinction an opportunity of obtaining the doctorate of medicine which they could in no other way reach, and of connecting themselves with an institution of much antiquity and interest. This end would probably be to some extent, at any rate, effected if, instead of sending for ten practitioners only to come up, and so limiting the candidates at the examination to the number of degrees to be conferred, a larger number were admitted, and a selection made upon well-defined grounds of professional distinction, and the possession of such superior knowledge as may be indicated by an examination of a higher order.

The Examination in Medicine and Midwifery for the Licences of the King and Queen's College of Physicians, Ireland.—The report is a favourable one. The examination is stated to have been long and painstaking; and the only adverse comments made are, that in the examination for the licence in medicine only a single pathological specimen was exhibited, no other provision being made for testing the knowledge of the candidate in pathology; and that in the examination for the diploma in midwifery, considering that it was solely for the purpose of testing competency in obstetrics, no attempt was made to determine if the candidates possessed any practical knowledge in midwifery, a pessary being the only instrument shown or about which questions were asked.

The Examinations of the Apothecaries' Hall, Dublin.—These examinations are somewhat severely handled by the Visitors, and evidently admit of improvement. The knowledge of the candidates on chemistry, botany, and pharmacy appears to have been well tested in the first examination, but the anatomical and physiological parts were inadequately examined upon. The oral part of the examination was limited to osteology, and no dissections were required; and in physiology the oral examination was limited to ten minutes. Only an hour was allowed for answering the written papers on anatomy and physiology. The second part, or final examination, was similarly imperfect; the clinical examination, in particular, being limited to the recognition of disease, without any further questions in regard to symptoms, prognosis, differential diagnosis, or treatment being asked.

Final Examination for M.B. in the University of Edinburgh.—The report on this examination is entirely satisfactory, and it seems indeed to be a very searching and efficient one, the only suggestion made being that in the clinical part one or two more cases might be given to each candidate to be investigated in the presence of the examiners.

The Previous Medical Examination of the School of Physic, Trinity College, Dublin.—The Visitors' report on this examination shows it to be a thoroughly good one, though no dissection was required. The chief point worthy of notice appears to be the system of marking. If the two examiners agree, the candidate passes or is rejected, as the case may be; but if they disagree, then the other members of the Board of Examiners are appealed to and settle the question. This is clearly hardly fair to the candidate.

DEATH DURING THE ADMINISTRATION OF ETHER.

We have received the following interesting "Report of a Case of Death, with Escape of Blood into the Trachea, during the Administration of Ether" from Mr. G. H. Bailey, anæsthetist to the Cancer Hospital and to the Dental Hospital of London, with notes by Dr. Benjamin W. Richardson, F.R.S.

On the 23rd June a man was brought into the operating theatre of the Cancer Hospital to have a portion of his tongue removed. There was nothing special in his appearance. He was thin and slightly pallid, but otherwise looked healthy. He was placed in the reclining posture on the table. His pulse was full and bounding; his respiration free. I first made him partially insensible with nitrous oxide, and then administered ether, (P.B.) sp. gr. 0·735, from a cone of lint covered with oil-silk, the plan I have adopted latterly, in preference to giving chloroform, for general anæsthesia. He struggled but slightly, and was soon under the influence of ether. The pulse was now full and regular; pupils contracted; respiration unoppressed. It was in all respects a typically good case. The screw-gag was placed in his mouth for commencement of operation, and the tongue transfixed with string. Mr. Irvine then cut away from the left side, and about two-thirds back, a good inch and a half of structure. One vessel bled freely, and there was a little welling up from another; but altogether the amount of blood lost was very small, taking the average of similar cases. I should think it was about five minutes from the commencement of the operation when the face assumed a specially dusky appearance. The pulse, however, was still remarkably good, but the respiration had become shallow, attended with a slight gurgling in the throat and a little effort to expel the blood. Cessation of respiration seemed imminent, so much so that I immediately removed the gag, pulled out the tongue, and carried on artificial respiration by Silvester's method. Breathing, however, soon ceased, although the pulse kept beating for, it seemed, some minutes. At the same time we used galvanism, and kept the head well down, but all to no purpose, although we persisted for fully half an hour.

My colleagues and myself felt we had here a rather interesting and, if a death from ether, an important case physiologically and practically, so that we determined to ask Dr. Richardson to assist us at the post-mortem. With his usual zeal he came, and the inquiry was made under his supervision.

T. B——, aged fifty-one, died at 5 p.m. June 23rd.

Autopsy, forty-eight hours after death.—From the right side of the mouth a small quantity of dark-coloured blood has flowed. Suffusion on the back extending to front of neck. Rigor mortis not strongly marked, but most in lower limbs. On opening the body, the blood escaping from the veins is fluid, dark, treacly, and yields bubbles of gas; the surface is studded with bright-shining particles of oily appearance. No odour of ether, or at least doubtful. Lungs very fully inflated, of a greyish colour. Good deal of fat round heart. Pericardium contains about a drachm of fluid. Right auricle, collapsed, contains a very small quantity of fluid, frothy blood. Not a drop of blood in right ventricle; walls of both very thin; valves healthy. About an ounce of fluid blood in the pulmonary artery. The left side of the heart has very little blood, perhaps about two fluid drachms; valves healthy. Endocardium extremely red, rather more so on the left side. Aorta contains a little dark blood, its lining membrane also intensely red. Brain-substance healthy, but grey matter very pale, indeed almost white. The pia mater is extremely congested, especially at base. The whole of the arterial circle of Willis and cerebral veins intensely full of dark blood. Membranes of medulla intensely injected; substance healthy. Ganglionic portions of brain and commissures perfectly healthy, and the ventricles free of fluid. Cerebellum, like cerebrum, healthy. Kidneys greatly congested; capsule in some parts adherent. Stomach contains small quantity of grumous fluid; no blood in œsophagus. On opening the trachea a clot of blood is found extending from the glottis into the trachea; it is about four inches long by a quarter of an inch in diameter. A little fluid blood, or dark-coloured serum, probably from two to three fluid drachms in quantity, is found below the clot in the trachea and bronchial passages. The mucous membrane is intensely red.

Such are the facts of the case. They are better left without any comment from me, especially as I am favoured with the following observations.

Note by Dr. Richardson.

The case recorded by Mr. Bailey is one of extreme interest. The mode of death seems to me, from all the facts I gathered from the different observers, to have been as follows. From the deep narcotism induced by the ether, the respiration for a moment became reduced in power, as is not unfrequent under this mode of general anæsthesia. During the artificial respiration a little blood escaped into the glottis and impeded the efforts of the operators in re-establishing natural respiration. They filled the lungs with air, but did not establish a return current; so the death became pronounced by asphyxia. The heart, as is common under such circumstances (when the lungs remain inflated), continued to beat until it collapsed from deficiency of arterialised blood.

I have no doubt the man would have recovered under the artificial respiration had the trachea been free of obstruction; and the practical lesson taught by the case is, that in future, whenever the respiration fails during an operation on the mouth and throat, the artificial respiration should be made with double-acting bellows from an opening in the trachea, with the head of the patient brought very low, so as to allow fluid to gravitate from the bronchial tract.

Physiologically, the case is of interest in that it has, unfortunately, enabled us to see, for the first time in the human subject, the precise conditions induced in the organism by ether administered to complete insensibility. The appearances are identical with those I have seen in the lower animals after death by ether. The blood fluid, the arterial blood dark, the cerebral arteries and veins charged with dark blood, the mucous membranes injected, and the pia mater of the brain, medulla, and cord intensely injected, but the cerebral mass itself white and bloodless. Long ago I classified ether with alcohol, amyl nitrite, and others of the same series, as an agent which by its action on the organic nervous supply of the minute circulation reduces the arterial tension, and produces narcotism by congestion of vessels and suspension of circulation through the cerebral mass. The case before us is a case in point. The whole external vascular mechanism of the cerebrum, cerebellum, and cord, was distended with blood; the whole of the internal nervous mechanism was bloodless. The facts have a further and important bearing on the suggestive researches and ingenious theories of Dr. Cappie upon the cause of the phenomenon of sleep. But the most interesting fact of all taught by the case is, that a perfectly bloodless condition of brain-substance may coexist with intense vascular congestion of the membranous vascular network, the same as coexists with that empty and contracted state of the vascular network which is induced by chloroform and the other narcotic agents of the chloride series. This is a new truth which must not be forgotten in future research.

NERVE-STRETCHING.

To the Editor of The Lancet.

Sir,—I have just been reading with much interest Mr. Callender's lecture on "Nerve-Stretching" in last week's Lancet, and his remarks on "the temporary numbing of the nerve-trunk so as to interrupt the chain of impressions" have brought to my mind a case where I was enabled to afford relief, which I think may be of some practical use. About three years ago I was in attendance upon a lady suffering from a very large fibroid tumour of the uterus. The pressure upon the sciatic nerve caused intense and I may say almost continuous pain down the thigh and leg, for the relief of which sedative applications were ineffectual. The patient being much emaciated, it occurred to me that I might numb the nerve by ether spray, and, having procured the necessary apparatus, I applied it for about two minutes along the course of the nerve in the thigh, and was agreeably surprised to find that, not only did it give instantaneous relief, but that for ten days there was no recurrence of the pain. I have since tried this treatment in cases of sciatica, and have recommended it to some practitioners, and in all the cases that I have heard of relief has been afforded.

There may not be anything original in this simple treatment, but as I have not seen it recommended in any work, I beg to submit it to you for publication should you think fit. I am, Sir, your obedient servant,

Richard Wolseley, M.D.,
Warley, 27th June, 1875. Surgeon-Major, A.M.D.

CATHETER STAFFS.

To the Editor of The Lancet.

Sir,—In The Lancet of June 19th, p. 876, Mr. Hulke states, "Mr. Teevan is under a misapprehension respecting Fergusson's catheter staff." This, he says, "was a great improvement upon the staff employed by the late Professor Syme, but it lacked a sliding catheter. Now this is just what it does not lack." I reply—1. In Mr. Henry Smith's description of Sir W. Fergusson's catheter staff, at p. 257 of his "Stricture of the Urethra," there is no mention whatsoever of a sliding catheter. 2. The catheter staff shown me by Mr. Henry Smith neither did nor could possess any sliding catheter. 3. From a report in The Lancet, vol. ii. 1854, p. 435, of a case of external urethrotomy performed by Sir W. Fergusson, it would appear that his instrument had no sliding catheter—"The silver catheter was now withdrawn and an elastic one of large size introduced." 4. The profession, I believe, knew of no staff fitted with a sliding catheter till Mr. Marshall described one in The Lancet for March 7th, 1857. The Lancet officially noticed Mr. Marshall's instrument, and called it a "New sliding staff for perineal section," vol. i. 1857, p. 186. 5. The works of Sir W. Fergusson and Messrs. Matthews make no mention of any staff with a sliding catheter, and they offer only Syme's staff for the performance of external urethrotomy. I remain, Sir, your obedient servant,

Portman-square, June 23rd. W. F. Teevan.

Obituary.

PROFESSOR OSWALD HOME BELL.

Many of our readers who are graduates of St. Andrews will hear with regret of the premature death of Dr. Oswald Home Bell, Professor of Medicine in that University, at the early age of thirty-nine. Dr. Bell was a son of Colonel Bell, of the Madras Artillery, and, after being educated at St. Andrews, commenced the study of medicine in the University of Edinburgh, where he graduated in the year 1857. After spending one or two years in the army, being attached to the Royal Artillery, he entered into practice in St. Andrews, in partnership with the late Dr. Adamson, who, like himself, was prematurely cut off in the midst of a most honourable and useful career. Dr. Bell soon established a leading position in St. Andrews, and was widely consulted in all parts of the country. In the year 1863, the Chair of Medicine was conferred on him, on the retirement of Dr. Day, and he fully justified the selection of the Government by his assiduous attention to his duties. As there is no medical school attached to the University of St. Andrews, Dr. Bell might easily, had he thought proper, have made his office a sinecure. But, instead of doing this, he at once commenced a course of lectures on popular medical and physiological subjects, suited to a non-professional audience, and soon gathered together large classes. In spite of the distractions of an extensive practice—for after his partner's death he had much more on his hands than he could well accomplish,—he never slackened in his professorial duties, or in keeping himself abreast of the most recent advances of science. Privately he was beloved and respected by all, and his early death will be deeply lamented. His last illness, which was of a somewhat obscure character, was long and protracted, and for many weeks it was known that his chances of recovery were almost hopeless.

Medical News.

Royal College of Surgeons of England. — The following gentlemen, having passed the required examinations, received the diploma in Dental Surgery at a recent meeting of the Board of Examiners:—

Frederick Canton, Great Marlborough-street; Edward J. M. Phillips, Liverpool; James L. Robinson, Cheltenham; Joseph I. F. Corbett, Cork; John M. Lipscombe, Alresford; George H. Harding, Stafford; Jack H. Whatford, Brighton; Walter H. Fox, Gloucester; George B. Pearman, Chelsea; Herbert H. Clifford-Eskell, Dublin; Augustus Cooke, Upper Norwood; Alfred A. Hart, Newington; Francis Youngman, Thornton-heath; Alfred Foss, Stockton; Theodore Abraham Bodecker, Newark; George Arthur Williams, Cavendish-place; Charles Edward White, Belgrave-road; William G. Morris, Winchester-street; John Carteighe, Stratford-place; Thomas Gaddes, Barkham-terrace; Thomas E. King, York; James Stocken, Euston-square; Robert Hall Woodhouse, Hanover-square; William C. S. Bennett, George-street; Alfred Allworth, Lyndhurst-road; James Williams, Walsall; Thomas Rowney, Hull.

Three other candidates were examined, but were not approved.

Apothecaries' Hall. — The following gentleman passed his examination in the Science and Practice of Medicine and received a certificate to practise on June 24th:—

Martin, John Michael Harding, St. Helen's, Lancashire.

The following gentlemen passed the Primary Professional Examination on the same day:—

Dobbie, Robert John Algernon, London Hospital.
Haines, William John, St. Bartholomew's Hospital.

Association of Sanitary Inspectors.—At the last quarterly meeting, held at Rothwell, of the Association of Sanitary Inspectors of the combined sanitary authorities in the counties of Northampton, Leicester, Rutland, and Bucks, under the presidency of Mr. Haviland, the medical officer of health for the combined area, the following resolution was adopted:—"That this Association, after very carefully considering the different systems of sewage disposal, is of opinion that it is desirable to represent to the delegates of the combined area the necessity of their determining on adopting some dry portable system, such as that of the Goux Company, under the entire superintendence of the inspector of nuisances, as the simplest system of disposing of village sewage."

Medical Appointments.

Beckingsale, D. L., M.D., C.M., has been appointed House-Surgeon to the Queen Charlotte Lying-in Hospital, vice Hart, resigned.

Birt, Mr. L. F. H., has been appointed House-Surgeon to the Royal Westminster Ophthalmic Hospital, King William-street, Strand, vice Alford, whose term of office has expired.

Butler, J., M.R.C.S.E., has been appointed Medical Officer of Health for the Long Eaton Urban Sanitary District: £25 per annum; acreage 2000; population 5000.

Collins, W. C. G., M.B., C.M., M.R.C.S.E., has been appointed Resident Medical Officer to the Swansea Hospital, vice Lloyd, resigned.

Craven, J., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Parish of Reay, N.B., vice W. Bruce, M.D., deceased.

Cross, F. R., M.R.C.S.E., has been appointed Resident Medical Officer to the St. Pancras and Northern Dispensary, vice Homan, resigned.

Dempsey, W. C., M.R.C.S.E., has been appointed Medical Officer to the Amalgamated Friendly Societies' Medical Association, Barrow-in-Furness.

Eaton, J., M.D., C.M., has been appointed Medical Officer of Health for the Cleator Moor Urban Sanitary District.

Edwards, R., L.R.C.P.L., M.R.C.S.E., has been appointed Resident Assistant Medical Officer to the Toxteth-park Township Workhouse, vice Ransford, resigned.

Fairbank, F. R., M.D., M.R.C.P.Ed., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer to the Doncaster Union Workhouse, vice Kiernan, resigned.

Gallimore, T., L.R.C.P.Ed., has been appointed House-Surgeon to the Metropolitan Free Hospital, Devonshire-square, vice Wattie, resigned, and appointed Assistant Medical Officer to the Central London Sick Asylum District Asylum, Cleveland-street.

George, Mr. W. H., has been appointed Assistant Medical Officer, Chorlton Union Workhouse, vice Davy, whose appointment has expired.

Hair, J., M.D., L.F.P. & S. Glas., has been appointed Medical Officer and Public Vaccinator for the No. 8 District of the Lexden and Winstree Union, vice Palmer, resigned.

Harvey, T., M.R.C.S.E., has been appointed Medical Officer for the West District of the Poplar Union, vice Fausset, resigned.

Hayman, H., F.R.C.S.E., has been reappointed a Medical Officer of Health for the Wycombe Rural Sanitary District.

Isaac, J. B., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Assistant Medical Officer to the Broadmoor Criminal Lunatic Asylum, vice Davies, appointed Senior Assistant Medical Officer to the Kent Lunatic Asylum, Barming-heath.

Jay, F. Fitz Herbert, L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Woodbury District of the St. Thomas Union, Exeter, vice Barton, resigned.

Jolly, A., L.R.C.S.I., L.R.C.P.Ed., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Drum Dispensary District of the Cootehill Union, Co. Cavan, vice Clarke, resigned.

Jones, D. R., L.R.C.P.Ed., L.M., M.R.C.S.E., has been appointed Medical Officer to the Llandrillo Friendly Society.

Manders, H., L.S.A.L., has been appointed Assistant House-Surgeon and Dispenser to the Kent and Canterbury Hospital, vice Sampson, resigned.

Merson, J., L.D.S. R.C.S.E., has been appointed Dental House-Surgeon to the Dental Hospital of London, vice Hepburn, resigned.

Miller, Mr. F. D., has been appointed Registrar and Chloroformist to the Evelina Hospital, Southwark-bridge-road, vice Sangster, resigned.

Morrill, A. H., M.R.C.S.E., has been appointed Resident Medical Officer to the Notting-hill Provident Dispensary and Maternity, Portland-road, vice Procter.

Smith, R. B., L.R.C.P.Ed., L.R.C.S.I., has been appointed Medical Officer and Public Vaccinator for the Burbage District of the Hinckley Union, Leicestershire, vice Ludlow, whose appointment has expired.

Tibbits, E. T., M.D., has been appointed a Physician to the Infirmary and Dispensary, Bradford, Yorkshire, vice Nicol, deceased.

Turner, E., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Kingswinford No. 1 District of the Stourbridge Union, vice Freer, resigned.

Warren, T., M.R.C.S.E., has been reappointed a Medical Officer of Health for the Wycombe Rural Sanitary District.

Yeo, G. F., M.D., C.M., has been appointed Professor of Physiology at King's College, London, vice Rutherford, appointed Professor of the Institutes of Medicine in the University of Edinburgh.

Births, Marriages, and Deaths.

BIRTHS.

Berry.—On the 22nd ult., at Wimbledon-hill, the wife of O. W. Berry M.R.C.S.E., of a son.

Cooper.—On the 30th ult., at Leytonstone, the wife of Frank W. Cooper, Surgeon, of a daughter.

Gayton.—On the 28th ult., at the Homerton Small-pox Hospital, the wife of Wm. Gayton, L.R.C.P., Medical Superintendent, of a daughter.

Kingsford.—On the 27th ult., at Upper Clapton, the wife of C. D. Kingsford, M.D., of a daughter.

Parsons.—On the 26th ult., at Sunnyside, Wimbledon, the wife of T. E. Parsons, M.R.C.S.E., of a daughter.

Philpots.—On the 22nd ult., at Moorecroft, Parkstone, the wife of John R. Philpots, L.R.C.P.Ed., of a son.

MARRIAGES.

Horton—Elliott.—On the 29th of May, at St. George's Cathedral, Freetown, Sierra Leone, James Africanus Beale Horton, M.D., Surgeon-Major Army Medical Department, to Selina Beatrice, third daughter of John Bucknor Elliott, Esq., Civil Commandant of the Western District of Sierra Leone.

Paul—Jennings.—On the 29th ult., at St. Mary's, Bootle, Ernest Watson Paul, L.K.Q.C.P.I., M.R.C.S.E., L.M., of The Green, Calne, Wiltshire, Medical Officer of Health for the Town, to Kathleen, second daughter of J. W. Jennings, Esq., of Bootle, Lancashire, and cousin of Lord Vyvyan.

DEATHS.

Brennan.—On the 21st ult., at Brixton-road, Surrey, George Brennan, M.R.C.S.E., in his 46th year.

Collins.—On the 22nd ult., at Edgeware-road, Judah Collins, L.S.A.L., aged 57.

Davies.—On the 23rd ult., at Bangor, Robt. Davies, L.R.C.P.Ed., aged 30.

Hancock.—On the 2nd ult., at East Budleigh, E. Hancock, M.R.C.S.E., aged 56.

Prankerd.—On the 20th ult., at Holland-road, Kensington, Emma, the beloved wife of Orlando Reeves Prankerd, M.D., aged 31.

Wright.—On the 25th ult., at Coonoor, Madras, Wm. Evatt Wright, M.R.C.S.E., Staff Surgeon, aged 30.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*]

BOOKS ETC. RECEIVED.

Mr. Morgan: The Skull and Brain.
Watts's Dictionary of Chemistry.
Ganot's Popular Natural Philosophy.
Dr. Taylor on Poisons.
Dr. Semple: Diseases of the Heart.
Mr. Ormsby: Deformities of the Human Body.
Mr. Griffiths: Lessons on Prescriptions and Prescribing.

Notes, Short Comments, and Answers to Correspondents.

Small-pox in Bristol.

Bristol has the reputation of having a sanitary organisation somewhat in advance of that which prevails in many other of our large towns, and this reputation would appear to be not undeserved, if its comparative immunity from epidemics of zymotic disease may be urged in its support. No town in the present day can, however, surround itself with a sanitary cordon, and so prevent the introduction of infectious diseases from without, even if perfection of sanitary condition could prevent their spontaneous generation within. Small-pox has in recent years been frequently introduced into Bristol; but the city has hitherto escaped an epidemic of the disease. During the last few weeks, however, small-pox has there shown an unusual prevalence, and since the beginning of April 26 deaths have been referred to this disease, against 5 in the first three months of the year, and corresponding with the number during the whole year 1874. When the disease was first found to be increasingly prevalent a few weeks since, the guardians, at the urgent request of the medical officer of health, appointed two additional vaccination officers to make a house-to-house visitation in that part of the city in which small-pox was prevalent, to ascertain the number of unvaccinated children. These officers reported at the end of the first week the discovery of 145 unvaccinated cases, many of which were of children under the age of six months, but in 63 of which notices of legal proceedings were served. It is matter for regret that this neglect of vaccination so frequently remains undiscovered until a spark in the shape of a case of small-pox causes an outbreak of the disease. The Vaccination Act in England is not efficiently worked, and hence we are continually subject to local epidemics of small-pox. If the responsibility for the carrying out of the Act could be shifted from the guardians to the different sanitary authorities, the influence of medical officers of health could more easily be brought to bear upon the present widespread neglect of vaccination.

Dr. Gairdner, (Glasgow.)—The communication arrived too late for insertion this week; but it shall be published in our next impression.

The Apothecaries' Society.

To the Editor of The Lancet.

Sir,—Doubtless there are some senior members of the Apothecaries' Society who would for obvious reasons suppress the good old custom of the annual herbarising dinner, which gives the opportunity of spending a few hours of social companionship—opportunities which in our profession are so rare, and which for good fellowship can scarcely be dispensed with.

Now, Sir, although I am one of the humble second-class members, I would strenuously support this so-called "intensely stupid herbarising dinner," and would very willingly contribute my portion when old Time shall place me in that position, and if necessary make due and careful provision for that so-called "great hardship," which most certainly will not creep upon me without due warning.

There is another incident to which I would venture to call attention. We are branded and scoffed at with being a trading body of professional men. I deeply regret this fact, and would wish to see the business removed from the Hall. I would suggest that the Company as a trading one retire. It has been many years found fault with by examining boards, and the time has undoubtedly come for its own dignity as a qualifying board to cease from selling drugs. If this cannot be accomplished, and we are still to keep "shop," pray let there be some young blood enter the circulation, which would be the means of making the great hardship complained of by "A Member" less felt, by increasing the dividends of many worthy practitioners, out of which profits the expenses of this dinner might come.

I am, Sir, yours obediently,
London, June 28th, 1875. Another Member.

The Potato Beetle.

Mr. W. V. Andrews, of Brooklyn, U.S., in a communication to Hardwicke's *Science Gossip*, denies that the *Doryophora* 10-*lineata*, in any stage of its existence, ever attacks the tubers of the potato plant. The eggs of the insect, he says, are laid on the leaves or stalks of the plant in early summer, the larvæ feed on the leaves exclusively, and the pupa is formed in the soil. "I see no reasonable ground of apprehension," concludes the writer, "that this beetle will ever find its way to Europe at all; but if it does, it will not be in a barrel of potatoes."

Aquarium.—We really cannot say where it may be obtained.

Californian "Oak Rash."

To the Editor of The Lancet.

Sir,—I should feel much obliged if you or any of your readers could give me any information on the following subject.

In California the people are commonly affected with a rash, which they call poison oak. In appearance it is like urticaria. Some who are affected by it get over it in about a week, and in others it lies dormant, breaking out occasionally. It commonly affects parts in which the skin is thin, as flexures of joints, inside of the thighs, face, &c., and on those parts exposed to the air. It looks much like erysipelas. Desquamation invariably follows. The itching and tingling are very severe, and there are many remedies to allay it—in one case apparently doing good, and in another having no effect. It is a popular notion that a small dwarf oak is the cause of it, which grows very plentifully in California, especially in the picnic grounds, and people become affected generally having been out to picnics and in the woods. I should be much obliged for any information on the subject. May it not be a vegetable parasite? I remain, Sir, yours truly,
London, June 22nd, 1875. F. E. T.

Chloroform in Parturition; its Effects on the Fœtus.

Dr. Sweifel, of Strasburg, submitted the placenta to analysis by distillation in a case where chloroform had been inhaled, and obtained chloroform, recognised by several accurate tests. He has also found that the urine of new-born children whose mothers had used chloroform reduces Fehling's solution, and has, moreover, observed that the expired air of such children has for several hours a well-marked odour of chloroform. Dr. Sweifel, arguing from these facts, concludes that the chloroform inhaled by the mother passes into the circulation of the fœtus.

Dr. Andrews.—The word "atrocious" used by Dr. Hardwicke in commenting on the conduct of members of the profession who have the misfortune to be concerned in inquests has now lost the charm of novelty.

The paper of *Dr. J. C. Ogilvie Will* (Aberdeen) shall appear in an early number.

Croup and Diphtheria.

To the Editor of The Lancet.

Sir,—The letters which have recently appeared in The Lancet on this most important subject cannot but prove highly interesting to the profession generally, and will, I trust, awaken a spirit of true and earnest inquiry.

I quite agree with Dr. Burney Yeo that those who are engaged in large general practice in the provinces have the best opportunities of acquiring useful practical information on the question at issue; and although the discussion has hitherto to a great extent been confined to "potent, grave, and reverend seniors" in the profession, yet I hope you will allow me space for a few remarks, as one who feels a deep interest in the subject under discussion, and who has had considerable experience in the study and treatment of croup and diphtheria.

Notwithstanding the dictum that "Fools rush in where angels fear to tread," and the probability that I shall be deemed impertinent in engaging in such an important controversy, yet, while the ant-hill represents the labours of the ants in the aggregate, we must not forget that each ant has had his share in the work, and so I think the modest but earnest endeavours of the humblest worker and observer can do something in adding to the accumulation of facts, and thus enable him to become a contributor to the progress of medical science, and to the realisation of its greatest aim—the welfare of humanity.

I really cannot imagine how anyone who has seen many cases of croup and diphtheria can look upon them as in any way identical, or even similar as diseases, and to my mind there is as great a difference between them as between an ordinary case of tonsillitis and one of scarlet fever. Our nomenclature is much at fault in denominating the varieties of so-called croup. But let us take a case of tracheitis or true croup, and contrast it with one of diphtheria. Tracheitis is, I contend, nothing but an acute, local inflammation of the mucous membrane of the windpipe, the tendency of which is to spread downwards, and characterised by the exudation of false membranes on the inflamed mucous surfaces. The incipient symptoms resemble those of simple cold, and, of course, become aggravated as the inflammatory process goes on, until the characteristic false membranes are formed, and the case of croup is established. It is needless to detail all the symptoms; but it must be borne in mind that the local inflammation may in some cases spread downwards from the glottis or larynx. Now, in this affection, which almost invariably occurs in children, we have nothing but the local sthenic inflammation, and the effects of this inflammation on the respiratory system &c.; no evidence of any *materies morbi;* no elimination of albumen in the voided urine; no very characteristic sequelæ, and nothing particular about the convalescence. The affection has been acute and local from beginning to end, and perfectly non-infectious.

On the other hand, diphtheria, whether it comes on in the child or adult, has its outset characterised by gradually increasing prostration and debility, and manifests indubitable evidences of toxæmia from the first. Then diffusive inflammation of the fauces, œsophagus, and respiratory tract usually sets in; the mucous membrane becomes covered with ash-coloured specks; lymph is exuded; false membranes formed on the tonsils and over the adjacent mucous membrane; and throughout the career of the attack the principal symptom is prostration—the prostration of a specific blood-poison. In almost every case we find albumen in the urine from the first, and the disappearance of this is, I believe, the best indication we can have of ultimate recovery. In croup, when resolution has taken place the attack is virtually over, but not so with diphtheria; too often the worst is to follow, and we may have deafness, blindness, loss of voice from paralysis of the soft palate, still worse, paraplegia, and an entire train of lesser evils. I have seen cases die from pure exhaustion long after all throat symptoms had abated, and I have seen fine young fellows lying as helpless as children from progressive paralysis very soon after an attack of diphtheria.

I quite agree with my esteemed friend, Dr. Carr, when he maintains that diphtheria is endemic and non-infectious; and I believe defective hygienic conditions, damp situations, badly-drained houses, and poor circumstances have much to do with its propagation. Brettonneau says that those who attend patients *cannot* contract diphtheria unless by actual contact, as of the diphtheritic secretion with an abraded mucous membrane, or with a part of the skin denuded of epidermis. As an evidence of its non-infectiousness (one of many I might adduce), I may first mention that I attended a family with diphtheria some months ago. This family lived some miles in the country, in a very isolated district, and occupied one of two cottages which were built together, and situated in a field. Although a father, mother, and five little children lived next door, not one of them ailed in the least; but three in the next house had diphtheria very severely. The youngest child died first, then the mother, and the son recovered after an attack of dysphagia, paraplegia, &c., which left him helpless for weeks.

As to the endemic character of diphtheria, I remember an old tumbledown row of houses from which I thought I was never going to eradicate it; but I found that all those who went away and remained got better, whilst some who came back became affected with diphtheria on their return.

I might say much on the mode of treatment &c. I have found most successful; but have trespassed too far on your valuable space already, and will reserve what I wish to say for another letter. Meanwhile, let me add, by way of conclusion, that I believe diphtheria to be endemic and non-infectious, and I maintain that diphtheria and croup are about as dissimilar as two diseases can be. I am, Sir, yours &c.,

R. A. Douglas Lithgow, L.R.C.P. Ed., &c.
North Brink, Wisbeach, June, 1875.

Boulimia followed by Polysarcia.

M. Lubelski, of Warsaw, has sent to the Academy of Medicine of Paris the description of a case of this kind. The subject is a woman, aged thirty-six, who, after two months' marriage, had nervous attacks, which were supposed to be owing to pregnancy, as she had not menstruated for some time. A craving appetite now supervened, and increased to such an extent that she ate from 14 to 16 lb. of meat per diem. No albuminuria nor diabetes. The patient now grew enormously stout, weighed about 18 stone, and could no longer walk. Around the waist, on a level with the umbilicus, she measured 44 inches. Various plans of treatment have been tried to no avail, and it was noted that the woman presented an abnormal tolerance of toxic substances. M. Lubelski thinks that the affection is of the neurotic kind, but refrains from offering a decided opinion. Messrs. Béclard, Personne, and Vulpian were appointed by the Academy to report upon the case.

Chloralum Lotion in Leucorrhœa.

To the Editor of The Lancet.

Sir,—It is with much pleasure that I can add my testimony to the use of chloralum as an injection in cases of leucorrhœa. For several years past I have used the remedy very largely in my practice, and, upon the whole, consider it one of the most useful compounds introduced to the profession. In that dreadful disease, cancer uteri, I have obtained good results in relieving pain and removing the horrid smell due to the disease; the strength of the injection employed being from one to two ounces of chloralum to one pint of water. In gonorrhœa in the male and female its action is most satisfactory, the male requiring about three drachms of chloralum solution to eight ounces of water; also fetor of the breath (cancrum oris) and spongy gums, when used as a gargle in the proportion of one to ten, the remedy is most beneficial. In the chronic diarrhœa and sweats of advanced phthisis I have given the remedy internally in half-drachm doses diluted with water, with a fair amount of success. The only drug I sometimes combine with chloralum in the form of injection or gargle is a safe quantity of extract of opium, previously dissolved in warm water.

With regard to chloralum wool, I use it constantly in cases of offensive discharges from the ear, to the comfort of the patient and those around him.

I am, Sir, yours truly,
Sunderland, June 29th, 1875. C. F. Nursey, L.R.C.P. Ed., &c.

A Licentiate.—The licentiates are invited to the *soirées* at the College, but not all of them at each *soirée.* We understand that the licentiates are so many that it is impracticable, on account of actual space alone, to issue invitations to more than a certain number to any given gathering, and the custom has been to invite them in different sections at different times.

Rumsey Testimonial Fund.

In addition to the amount already acknowledged (£573 6*s.* 6*d.*), the following subscriptions have been received:—

Subscriptions may be forwarded to Dr. Buchanan, New Government Offices, Whitehall; to the Honorary Secretary; or to Messrs. Robarts, Lubbock, and Co., Bankers, 15, Lombard-street, E.C. Cheques should be made payable to the Rumsey Testimonial Fund or bearer, and crossed "Robarts, Lubbock, and Co." Post-office orders should be drawn on the Curzon-street Post-office, and forwarded to the Honorary Secretary, W. H. Corfield, M.A., M.D., 10, Bolton-row, Mayfair, W.

Staff Surgeon Mulvaney's interesting communication shall receive early attention.

Bloodless Surgery.

To the Editor of The Lancet.

Sir,—The bloodless amputation of the extremities may be performed, without having recourse to Esmarch's method, by a plan I have successfully adopted for more than eighteen years. Apply the tourniquet loose in the usual situation, elevate the whole limb so that every part of it may be above the level of the heart, and keep it elevated for about five minutes. The limb becomes almost bloodless, and if, while the limb is still raised, the tourniquet be well tightened, it will be found that when the amputation is performed not an ounce of blood will be lost.

In your volume for 1856 will be found an account of the amputation of both legs on the same day, performed by me at the Purton Workhouse, in which this method was first adopted, and with entire success. The man recovered rapidly, and was about in five weeks after the operation. Since then I have always adopted the same plan when the saving of blood was an object. In cases of amputation after injury in robust subjects, when there has been no previous hæmorrhage, I do not think the loss of blood actually in the limb any disadvantage.

I am, Sir, your obedient servant,
R. H. Bakewell, M.D., M.R.C.S.
Dunedin, New Zealand, April 12th, 1875.

Zymotic Disease in Keighley.

The *Keighley News* reports that "on account of the highly infected state of the town from small-pox and fever," the Clerk of the Peace "has excused the attendance of all the Keighley jurors who had been summoned to appear at the Bradford Sessions." Although the fatal epidemic of small-pox appears to be declining, the registrar's return for the week ending 24th June showed that of 22 deaths in the town from all causes, 4 resulted from scarlet fever, 2 from small-pox, 2 from whooping-cough, and 1 from enteric fever. No less than 41 per cent. of the deaths in the week were referred to four of the principal zymotic diseases. There appears, therefore, to be some ground for describing the state of the town as "highly infected."

Medical Preliminary Examination.

To the Editor of The Lancet.

Sir,—I should be very much obliged to you if you will allow me, through the medium of your columns, to offer (with all due respect to the honourable examiners of the College of Preceptors) a suggestion which, if carried into effect, appears to me likely to prove of the utmost importance to intending candidates. What I suggest is that a plan might be adopted in having a third examination of the College of Surgeons in the course of a year. It might be held with great benefit early in September, in which case the unsuccessful candidate at June would in all probability meet with success in September, and thus obtain his admission to one or other of the London hospitals in October. It has often occurred to me with what advantage and pleasure this new plan would be received (were it adopted) by many such candidates.

Hoping my suggestion on such an all-important subject may be deservedly brought into notice, I remain, Sir, your obedient servant,
Croydon, June 22nd, 1875. An Anxious Promoter.

West Coast.—It is always a difficult matter to give advice on such a subject. What are our correspondent's own feelings in the matter? If he likes a roving life, and has no intention of marrying, the service offers many attractions and comforts. Although it cannot be contended that the station named is a healthy one, it is certain that it has been much maligned. On the other hand, the material advantages possessed are not often relinquished for such an alternative. There are many more eligible localities open to our correspondent (with his means) than the place he now writes from.

Section Cutters.

To the Editor of The Lancet.

Sir,—A very serious objection to Dr. Fleming's machine will at once occur to anyone who has done much work with the freezing method, in that the machine must require constant attention until the tissue is frozen and the sections are cut. In a University laboratory this is all very well; but for workers who are at the same time subject to the exigencies of practice the machine will be a constant source of disappointment. In the last number of "Humphry and Turner's Journal" I describe a new section-cutter, which obviates this objection. When the tissue has once been frozen, it will keep so for at least twelve hours, and for a week if the machine be placed in a Norwegian chamber. Having the section-cutter screwed to the table has not been found by me to be a disadvantage; but, on the contrary, a very great advantage, as it leaves both hands free—a matter of the greatest importance in cutting fœtal sections, where the tissues are not continuous.

Yours &c.,
Birmingham, June, 1875. Lawson Tait.

R. S. V. P.—Aloes is generally thought or said to be contra-indicated in cases of piles; but there is nothing absolutely to prevent its use in the hands of a judicious practitioner. According to Stillé, there is a form of piles which aloes is said to cure—one connected with a relaxed state of system, and of the rectum in particular. Christison, too, says that associated with hyoscyamus it may be given even to patients with hæmorrhoids.

Mr. Lindsay and the Coroner's Court.

We must decline to insert any more letters from Dr. Hardwicke's deputy.

Laryngeal Phthisis.

To the Editor of The Lancet.

Sir,—Two sufferers under my care have derived such marked relief from belladonna that, for the sake of the poor patient about whom "General Paresis" writes, I trouble you with a line. The dose of this palliative has been ten or twelve drops of a strong tincture prepared from the fresh plant, taken on a piece of sugar, and allowed to dissolve in the mouth, say three, four, or five times in twenty-four hours. The ordinary tincture may perhaps prove effectual. If it produces the characteristic dry throat of belladonna, the dose may be diminished. Hyoscyamus and other medicines of the narcotic class have in my experience had none of the effect of belladonna; yet, alas! the patient ultimately ceases to find relief from it also.

Yours faithfully,
June 25th, 1875. W. Wilberforce Smith, M.D.

Demarquay.

In consequence of the pressure on our space this week, we are compelled to postpone the publication of an obituary notice of the late M. Demarquay.

Mr. T. Finlaison.—We see nothing unprofessional in the letter.

German Medical Literature.

To the Editor of The Lancet.

Sir,—As I am aware that many of your readers are German scholars, I desire, through the medium of your columns, to endeavour to obtain some information. I am engaged in some researches which necessitate reference to German medical and scientific works, and I am constantly arrested by words not to be found in any dictionaries that I am acquainted with. In order to consult German medical works, is it absolutely necessary first to make for oneself a dictionary of all terms used in anatomy, physiology, and medicine, or are there any works published which would save the student this task? Hoping this may catch the eye of some German scholar,

I remain, Sir, yours &c.,
June, 1875. Fatherland.

Waking the Dead.

The registrar of Keady district, Armagh Union, illustrates the pernicious effects of that barbarous custom, "waking the dead," by the following narrative:—The first fatal case from influenza occurred in a man on the 9th March. His remains were kept for two nights in a small room, greatly crowded by his friends and neighbours. Decomposition of the body set in early, the fetor from which produced a sickening and depressing effect on those present, and it became so overpowering at his burial that the clergyman could scarcely finish the reading of the service. The consequence has been that a large number of those who attended his wake have suffered from blood-poisoning with disease of the lungs; his wife died of it on May 27th, while two of his children, his brother-in-law, and sister-in-law, and many others are dangerously ill of the same disease. A better example of the evils of "waking" could scarcely be produced.

Mr. Holderness is thanked for his communication.

The Primary Examination for the Fellowship of the College of Surgeons.

To the Editor of The Lancet.

Sir,—I have been asked by several medical friends regarding the opinion I had formed of the examination recently held for the F.R.C.S.; and having had experience as an examiner in Surgery and Surgical Anatomy on behalf of the Calcutta University, and, after an absence of twenty years from this country, passed the late first and second examination for the Fellowship, I should, doubtless, be able to form a tolerably correct view as to the matter, particularly to that part of it referred to by your correspondent, "W.," of the 5th inst.

In the first place, I would beg to remark that I believe I express the opinion of all the candidates who went up for these examinations when I say that nothing could have exceeded the consideration and kindness shown by the examiners towards the candidates, and, so far as I could ascertain, the questions they put to us were, as a general rule, clear and to the point. There could be no mistaking their meaning.

I cannot agree with "W." regarding the written questions in Physiology. It is true they were unlike those usually given on the subject; but this is surely rather a merit than otherwise on the part of an examiner so long as the questions admit of a definite answer. My experience of the examination for honours in the Calcutta University leads me to believe that it is desirable in high class examinations not to give more than three questions in Physiology and the same number in Anatomy. I should, in fact, be inclined just to reverse the conclusion arrived at by "W." on this point, and think that the *lucky* man has a better chance of getting through if asked half a dozen questions than if set down to answer only two or three. It seems to me, however, very desirable that the whole of one morning, and in fact as much of the day as the candidate can reasonably require, should be allowed him for his written examination in Anatomy and Physiology, and that these papers should hardly be given on the same day, and still less in one afternoon. And this leads me to what I conceive to be the defect in the existing system of examination. There is not enough time given to it; for anyone who has had experience in these matters must feel that men differ considerably as regards their temperaments and powers of answering questions, so that it seems hardly fair to handicap them all equally as to the time in which they are expected to satisfy an examiner as to the amount of knowledge they possess. One man goes up full of confidence to an examiner; another is nervous, falters at his first question, and feels he has only a few minutes to recover his position; before he has done so the bell rings, and, with the sense of failure hanging over him, he finds himself before another set of examiners. And thus it comes to pass that sometimes the "best students in Anatomy and Physiology are referred." Nevertheless, the issue of the examination is often a most serious matter, not only to the individuals concerned, but, over and above this, the system employed in examining will directly control for good or for evil the system employed in learning and in teaching—in fact, will influence to a great extent the well-being of the profession.

The question as to improving the existing state of things seems to me to be a very simple one; for there can be no difference of opinion regarding the truth of the remark made by "W.," that "the examiners should exercise the option of examining a man until they have satisfied themselves of his possessing sufficient knowledge or otherwise." But this process necessarily often requires time, and it seems hardly possible that it can pay the examiners, as at present constituted, to devote more of their time than they now do to these examinations. It probably remains, therefore, for the candidates going up for the F.R.C.S. to pay higher fees if they would retain the present form of examiners, or else the Council of the College of Surgeons must appoint men as examiners who can devote all the necessary time to the subject; for I cannot but think that the existing system requires reform in this direction. The profession have a right to feel convinced that every candidate going up for examination shall have his knowledge fully and fairly tested. It is hardly in the nature of things to expect that the rejected candidates will feel sure that they ought to have been referred. The system of awarding marks and other matters of detail noticed by "W." would probably follow if changes were made in the direction I have indicated; but the result would, I believe, be that fewer men than at present would pass. We do not, in truth, want better examiners than those we have. I do not conceive it is possible to procure them; but we do require more of their time, more perhaps than they are willing or able to give.

Lastly, I think that the College Council should distinctly declare their intention as to whether candidates in future are to be examined or not in Comparative Anatomy. I remain, Sir, yours faithfully,

Grosvenor-street, June 22nd, 1875. C. Macnamara.

To the Editor of The Lancet.

Sir,—I cannot refrain (considering the importance of the subject, and the attention it has of late received in The Lancet from both correspondents and in your able leader) from making a few remarks on the Fellowship of the Royal College of Surgeons.

No one who highly esteems the profession of surgery would for a moment wish the standard of the examination to be reduced; but "W." is perfectly correct when he criticises the absurdly unjust and uncertain method of deciding upon a candidate's merits in the answers to the paper. What can be more ridiculous than to consider two such questions as those last given in Anatomy as a test of a man's knowledge of such an extensive subject? Again, exception may well be taken to the apparently useless nature of the questions themselves, which, while easy of solution to a student who has crammed a little anatomy, are completely devoid of interest from a surgical point of view. There is no doubt whatever that the hurried manner in which the *vivâ voce* part of the examination is carried on must lead to many an error, otherwise avoidable, and leave many examiners in doubt as to the real knowledge of the candidate. The extreme uncertainty of the College examinations is, in reality, the subject of constant remark. It is within my experience that on one occasion a gentleman wishing, after a lengthened period of professional experience, to adorn himself with the honoured title of "Fellow," refreshed his memory with special reading and three months' dissection. He was referred on the primary examination, and had the pleasure of seeing young students, professional novices, pass the half-way house to that distinction which Sir Benjamin Brodie first instituted as an incentive to *superior surgical attainments*, and an instrument whereby to improve the position of the profession.

Let us now see how far our College of Surgeons is at present elevating the profession. An examination of the rules for admission to the Fellowship shows that there are three ways in which that diploma may be obtained. Firstly, as a junior at the age of twenty-five; secondly, as a member of eight years' standing (formerly twelve); and thirdly, by election as a member of the year 1843. Now, the last of these conditions implies that a man has had a long and honourable experience of his profession, attested, of course, by credible authorities. The other two conditions apply to individuals who take the Fellowship by examination only. The first of these includes men who have only just completed their studies, and entered perhaps upon the practice of their profession, or, in other words, commenced what is looked upon by the greatest authorities as the only true experience, matured observation. These are the men elected by the College of Surgeons upon whom to confer the greatest honour the Corporation can bestow, which, upon their passing successfully what is termed a *stiff* examination, they duly receive. The disgust of the seniors in the profession is no secret at the elevation to the Fellowship of those who have but recently emerged from the state of pupilage, and whose experience as surgeons must closely assimilate to the military experience of Artemus Ward when created a Brigadier-General. I need not say that all who think the standard of the Fellowship should be maintained deprecate the course taken by the College, and sincerely regret the admission to the grade of Fellow of those of such an early age. Of course the eight years' period gives an undoubted opportunity to members intending to seek the higher position to ripen their knowledge and extend greatly the experience of student life; but the reduction of the term for twelve years was certainly a step in the wrong direction.

Your correspondent, "F.R.C.S.," speaks justly of the degradation of the knowledge of anatomy amongst surgeons caused by the present system, and in so doing shows how a senior must be placed at a disadvantage compared to the student fresh from the dissecting-room, in the present primary examination, at which the one set of candidates appear clad in the knowledge which repeated and confirmed experience has taught them to consider anatomically necessary for the practice of the profession; the other armed with all the tips of the dissecting-room and other artificial aids to memory, so commonly practised, with the last favourite theory of this or that examiner, all too surely to become a chaos before the advent of the pass examination.

Let us hope that the Visitors from the General Medical Council will recommend and be able to carry a system of improved and more justly arranged examinations, that the item of experience shall have its due weight, and that in future there may be more certainty of passing a really good man, and of not unjustly referring one who is under present arrangements simply unlucky. If the General Medical Council cannot obtain for the profession the proper ordering of its examinations, then it is surely time that State interference should secure to the public that surgical experience and ability which now seem likely to be on the wane, to be replaced by a youthful false confidence and self-asserting importance, the obtrusive nature of which is only equalled by its utter incapacity to meet the serious demands which will be made upon it. Your obedient servant,

June, 1875. Chirurgeon.

To the Editor of The Lancet.

Sir,—Your correspondent, "F.R.C.S.," who objects that the Fellowship is now made an examination for students, instead of for practitioners, seems to me in his remarks as if he had not a clear enough ideal of what a superior diploma should be. It may be either a test of larger acquirements, in which case the more severe the ordeal the more valuable success; or it may be a mark of social and professional standing, pointing out merely that its owner has undertaken to practise in a particular way, has enjoyed certain advantages to fit him for such practice, and is not below the average in the way he has used them. If the Fellowship is to belong to the former class, the examinations should be made as stringent as can be, and men should be allowed to face them at the time they are best able to do so. If the latter kind, then let the standard be lowered to suit the memories of those whose knowledge has rusted in absence from the centres of scientific progress; but hedge it round with restrictions such as those which accompany the higher diplomas of the College of Physicians.

I am, Sir, yours &c.,

June 21st, 1875. Another F.R.C.S.

Metropolitan Mortality in Childbirth.

During the last two weeks of June no less than 30 deaths occurred in childbirth within the metropolis, 15 of which were referred to puerpera fever; whereas the corrected average weekly number from this disease in the corresponding period of the last ten years is but seven. Puerpera fever has been fatally prevalent in South London, especially in Newington where scarlet fever has also been epidemic.

Tablespoons and Teaspoons.

To the Editor of The Lancet.

Sir,—In the days of our great-grandfathers a tablespoon held exactly half an ounce. A modern tablespoon holds nearly twice as much. Yet the modern physician constantly prescribes a tablespoonful when he means half an ounce, and the measuring glasses sold by the modern chemist are graduated in the ancient way. In like manner a teaspoonful often means a drachm, though the modern teaspoon holds nearly two drachms. I have known serious consequences result from prescribing doses by spoonfuls. Those medicine glasses ought to be interdicted.

I am, Sir, yours faithfully,

St. James's-square, June, 1875. J. C. Whishaw, Surgeon-Major.

An Opening for Medical Women.

If the time should ever come when the portals of the profession will be thrown open to women, a good field for those who succeed in obtaining qualifications will be found in Constantinople in the medical supervision of the numerous harems existing there. It is stated that Madame Bres, the first lady to obtain a medical degree at the College of the Sorbonne, Paris, has declined an offer of 40,000 francs a year as physician to the Sultan's harem, on condition of never going outside the building. She will attend the harem, but will practise in Constantinople like other doctors.

Davey Defence Fund.

Dr. Davey begs to tender his most earnest thanks to those members of the medical profession and other friends who have responded to the appeal from his Committee, not only for their liberality, but also for their kind expressions of sympathy, which have been a source of great gratification to him in his trouble and anxiety.

Dr. Davey most gratefully thanks the Chairman, H. Davies, Esq., M.D., all the members of the Committee, and F. J. Reilly, Esq. (Hon. Secretary and Treasurer), for their great kindness and untiring energy on his behalf, which he can never forget or in any way repay; and also the Editor of The Lancet for so kindly inserting the appeal and lists of subscribers in his valuable journal, and receiving subscriptions.

Florence Villa, June 29th, 1875.

Boracic Ointment.

To the Editor of The Lancet.

Sir,—I have had a boracic ointment prepared as prescribed by Professor Lister in The Lancet of June 5th, but found it so hard that spreading it was impossible. The chemist with whom I deal suggested the addition of two drachms of glycerine, which is a decided improvement to the prescription in every way.

I am &c.,

Liverpool, June 15th, 1875. W. Macfie Campbell.

Communications not noticed in the current number will receive attention in our issue of the ensuing week.

Communications, Letters, &c., have been received from—Prof. Turner; Dr. Corfield, London; Dr. Gairdner, Glasgow; Staff Surgeon Mulvaney, Southsea; Dr. B. W. Medical Diary for the ensuing Week.

Monday, July 5.

Royal London Ophthalmic Hospital, Moorfields.—Operations, 10½ a.m. each day, and at the same hour.

Royal Westminster Ophthalmic Hospital.—Operations, 1½ p.m. each day, and at the same hour.

St. Mark's Hospital.—Operations, 9 a.m. and 2 p.m.

Metropolitan Free Hospital.—Operations, 2 p.m.

Royal Institution.—2 p.m. General Monthly Meeting.

Tuesday, July 6.

Guy's Hospital.—Operations, 1½ p.m., and on Friday at the same hour.

Westminster Hospital.—Operations, 2 p.m.

National Orthopædic Hospital.—Operations, 2 p.m.

West London Hospital.—Operations, 3 p.m.

Wednesday, July 7.

Middlesex Hospital.—Operations, 1 p.m.

St. Mary's Hospital.—Operations, 1¼ p.m.

St. Bartholomew's Hospital.—Operations, 1½ p.m., and on Saturday at the same hour.

St. Thomas's Hospital.—Operations, 1½ p.m., and on Saturday at the same hour.

King's College Hospital.—Operations, 2 p.m., and on Saturday at 1½ p.m.

Great Northern Hospital.—Operations, 2 p.m.

University College Hospital.—Operations, 2 p.m., and on Saturday at the same hour.

London Hospital.—Operations, 2 p.m.

Samaritan Free Hospital for Women and Children.—Operations, 2½ p.m.

Obstetrical Society of London.—8 p.m. Adjourned Discussion on Puerperal Fever.—Some interesting Specimens will be exhibited at the beginning of the meeting.—The Discussion on Puerperal Fever will then be resumed.

Thursday, July 8.

St. George's Hospital.—Operations, 1 p.m.

Royal Orthopædic Hospital.—Operations, 2 p.m.

Central London Ophthalmic Hospital.—Operations, 2 p.m., and on Friday at the same hour.

Friday, July 9.

St. George's Hospital.—Ophthalmic Operations, 1¼ p.m.

Royal South London Ophthalmic Hospital.—Operations, 2 p.m.

Saturday, July 10.

Royal Free Hospital.—Operations, 2 p.m.

Charing-cross Hospital.—Operations, 2 p.m.

NOTICE.

In consequence of The Lancet being frequently detained by the Post Office when posted for places abroad *more than eight days after* publication, subscribers and others are reminded that such copies can be forwarded only as book packets, and *prepaid* as such.

TERMS OF SUBSCRIPTION TO THE LANCET.

Post free to any part of the United Kingdom.

One Year	£1 12 6	Six Months	£0 16 3

To the Colonies and India.

One Year	£1 14 8

Post Office Orders in payment should be addressed to John Croft, The Lancet Office, 423, Strand, London, and made payable to him at the Post Office, Charing-cross.

TERMS FOR ADVERTISING IN THE LANCET.

Lettsomian Lectures
ON THE
SURGERY OF THE ARTERIES.

(ILLUSTRATED BY TWENTY-SEVEN OPERATIONS OF
LIGATURE BY THE AUTHOR, AND OTHER
CASES OF DISEASE AND INJURY.)

Delivered before the Medical Society of London, Jan. 1875,

By C. F. MAUNDER, F.R.C.S.,
SURGEON TO THE LONDON HOSPITAL.

LECTURE III.—Part II.

ON LIGATURE OF A MAIN ARTERY TO ARREST ACUTE TRAUMATIC INFLAMMATION.

However pathologists and physiologists may explain inflammation, however complex may be the process, whatever share in its production may be ascribed to the vascular system, to the nervous system, and to the tissues themselves the seat of it, I presume all will admit that an excess of blood is brought to the part. The experience of practitioners in the healing art had from time immemorial taught the value of the withdrawal of blood as a remedy for certain inflammations. Thus we have arteriotomy, venesection, the use of leeches, &c. But all these methods have this disadvantage in common—they *remove* blood from the system. Obstruction of the main channel, on the other hand, only *withholds* it from the inflamed part, and may be likened to dry cupping, by which the blood is diverted into other channels *temporarily*, and thus the inflammation is, as it were, starved. Lawrence says: "Blood is the material by which the increased action of the part is maintained. In the figurative language, which the obviously increased heat has suggested, one may say that it is the fuel by which the fire is kept up. If one could completely command the supply of blood, the increased action might be effectually controlled or arrested."

In considering the propriety of placing a ligature upon a main artery with a view to arrest acute traumatic inflammation in the part beyond, various questions must be entertained. First, the *possible* and *probable* result, if the case be treated on general principles hitherto accepted; secondly, the effects of the ligature (upon arteries such as the femoral and brachial) *immediate, intermediate,* and *remote.* On the other hand, in contemplating, in not a few instances, the effect of acute inflammation, of the knee-joint for example, subsequent to a wound of the same, the prospect is not at all cheering; and I know of no case in surgical practice of injury to a limb, not requiring immediate amputation, which excites more anxiety in the mind of the surgeon for the welfare of his patient than traumatic inflammation of this joint. Its effects, both local and general, are quickly manifested. Swelling, redness, and pain, precursors of suppuration, attack the joint and the limb both above and below, while traumatic fever runs high. After the lapse of a few days pus is formed in and about the joint, and for weeks, while the articulation is being destroyed, suppuration spreads and burrows up and down the extremity. During this period the patient's powers, both nervous and vascular, are becoming exhausted by pain and loss of sleep and appetite, consequent on the progressive destruction of the joint structures, as well as by the more or less profuse suppurative discharges. All this time, too, he has been exposed to the risk of erysipelas and pyæmia; and at length, to escape death from hectic, he submits to amputation, with a poor chance of recovery.

W. D——, twenty-eight years of age (Case 17, Table of Arteries*), became the subject of acute suppuration and sloughing of the soft parts of the hand and forearm, and disorganisation of the wrist-joint, associated with recurring hæmorrhage. To prevent further bleeding, and to remove structures damaged beyond useful repair, I advised amputation; but the patient declined, and I was obliged to be content with ligature of the brachial artery. He died of pyæmia on the eleventh day. No sooner had the operation been performed than inflammatory symptoms abated: swelling disappeared; suppuration, which had been profuse, was reduced to a minimum; sloughing ceased, and granulations quickly arose. I must say I was somewhat surprised at this beneficial result of the ligature, for the parts were so damaged by the previous inflammatory action, added to the injury, that I thought it likely gangrene rather than repair might result.

But it sometimes happens that the result of such an accident is still more disastrous, the patient dying after weeks of suffering in possession of the damaged limb, because no opportunity for amputation, with the hope of a successful result, had presented itself.

H. P—— (Case 9), a man aged forty-seven, was admitted on March 9th, 1867. He had sustained a severe squeeze of the knee. Suppuration up and down the limb and disorganisation of the joint followed; but the man was too ill to be submitted to amputation, and he ultimately died of hæmorrhage.

On the other hand, and under the most favourable circumstances that can be anticipated, the prospect is gloomy. A patient may recover with his joint more or less anchylosed and distorted, and the limb more or less useless in proportion to the degree in which its various component parts have been involved in the inflammatory process.

Peter J——, aged twenty, was admitted on November 6th, 1873, having received an injury to his left knee ten days before. In about a fortnight after the accident the knee-joint was laid open, and a large quantity of pus came from it. He was in the hospital six months, during which period very many incisions were made here and there to let out the matter, and drainage-tubes were used from time to time. For many weeks from three-quarters to a pint of pus was discharged twice daily. He ultimately recovered, with anchylosis. You will presently see this patient, but I fear will be able to form a very inadequate idea of his former condition judging from his present shapely and useful limb. This happy result is due to the great care and attention bestowed for weeks and months upon the case by my house-surgeons (Messrs. Mitcheson and Kershaw) and dressers (Messrs. Jones, Treeves, Needham, Snell, and Harvey).

It would be out of place to discuss here the treatment of disorganised joints with a view to prevent displacement of bones and consequent inutility. Suffice it to say that, in the instance of the knee (a joint especially liable to luxation) that you will see to-night such unpleasant accident has been prevented, and, anchylosis being necessary, the proper angle (a most essential point for the patient's comfort in progression) has been attained.

John P——, aged twenty-seven, was in the hospital at the same time as the former patient. Incisions about the joint were made, and a drainage-tube was used once. The inflammatory action of a comparatively mild character was more restricted to the neighbourhood of the joint than in the former case. From time to time a fresh attack of inflammation occurred, and these kept him in the hospital almost as long as the above patient who suffered so severely. Even now, twelve months since he left the hospital (March 18th, 1873), the limb has not recovered itself, while that of his fellow-sufferer is most useful. In this case an excess of synovia was the chief secretion from within the joint, associated with a little suppuration outside the capsule. You will see that the man has a firmly fibrous anchylosed joint; and he is an example of the injurious influence of a constitution spoiled by intemperance, upon local injury.

In rare instances—so rare, indeed, that they can scarcely be allowed to influence our prognosis—the patient escapes with a comparatively sound joint. A. B——, about eighteen years of age, sustained a blow upon the knee, followed by suppuration within the joint. This was evacuated by an incision on the outer side, and the patient was quickly well. The girl has perfect use of the articulation.

I especially invite your attention to these three patients to-night, because they were all under care at the same time, under the same roof, under the same surgeon, under the same atmospheric and hygienic conditions; but differed in one grand and all-important feature—in constitution. Each illustrates a stage of the disease which it is important to recognise during its progress, with a view to prognosis.

---

* The Lancet, Jan. 9th, p. 39.

The young woman has recovered, probably without a trace of the result of the injury existing to-day; the young man (of intemperate habits), while showing comparatively slight signs of local mischief, suffered severely in his general health, and even now repair is not complete; but the patient whose limb it seemed, to most who saw it, impossible to save, and which was twice condemned by my experienced medical friend, Mr. Stilwell, of Epsom, survives. It will be difficult even for those who saw him at his worst, and almost impossible for any who never saw him, to credit the transformation. The reasons of my withholding operative interference—either ligature of the femoral or amputation—were, his cheerful and hopeful disposition, a clean tongue, good nights, and never-failing appetite. But, above all, although the cartilages were destroyed early in the progress of the case, and the articular ends of the bones were exposed, these latter never became involved in the inflammatory process, and he was always free from "starting" pains. This symptom is evidence of disease which very often leads to operative interference, occasionally to death. On the other hand, we had to combat a most profuse discharge coming from all parts of the limb, and a disorganised knee-joint. (It will be out of place to discuss here, in connexion with profuse suppuration, how far a large supply of aliment favours this; but I think it worthy of consideration whether or not we overfeed some patients.)

The picture I have drawn, I believe truthfully, of the probable consequences of traumatic suppurative inflammation of the knee-joint is very discouraging. Can we hope for better things from ligature of the main artery. I think I have proved it.

I will now consider the possible effects—immediate, intermediate, and remote—of ligature of the vessel.

The *possible immediate effect* is gangrene of more or less of the limb, varying from the shriveling of a toe to death of the whole leg as high as the ligature. But this is scarcely likely to happen, because, an excess of blood having been now sent to the part, the collateral circulation may be regarded as already in some measure established. Case 21–22 in the Table of Arteries, a female aged forty-nine, in a very depraved state of health, and the subject of diffuse cellulitis with extensive sloughing about one foot and ankle, was submitted to ligature of the anterior and posterior tibial arteries of the same side, to arrest recurring hæmorrhage, she at the time being too weak for amputation. The acute symptoms subsided at once, and hæmorrhage did not recur. She soon died, and the whole foot and ankle seemed to have lost their vitality; but whether any part of this was due to the ligature it is impossible to say, sloughing having already commenced previous to the operation.

The *possible remote effect* is a permanent weakening of the limb, rendering it less valuable as an organ of progression, and, by lowering its vitality, making it less able to bear changes of temperature or to resist and repair injury and disease. I must repeat, as worthy of special notice, that in the case of the child already mentioned, within a week of the operation a slough formed on the heel from direct pressure. Knowing how slowly such accidental wounds often heal, I feared that in this instance it would be slower still. I was agreeably surprised to find that my anticipations were not realised: the sore closed quickly.

The *possible intermediate effect* is hæmorrhage at the seat of ligature, from either the proximal or the distal side. (The former complication requires a reopening of the wound, and search to be made, under difficult pathological conditions, for the bleeding orifice, that a ligature may be reapplied; or, if this cannot be accomplished, the trunk of the vessel must be exposed as near as practicable to the bleeding point, and a thread be passed around it. The latter accident will probably be combated by a well-applied graduated compress and bandage.) This subject was fully discussed and illustrated by cases in my former lecture.

Besides the above-mentioned possible consequences of ligature of the superficial femoral, we must not neglect to inquire into the influence of the operation upon the process of repair necessary to the restitution of the injured limb to health.

In the Paris revolution of 1830 Jobert tied the femoral artery[*] (I presume the common femoral is meant), with a view to cut off the supply of blood from this region brought by the profunda, for hæmorrhage in a case of gunshot fracture at the neck of the femur. Jobert remarks that the operation acted as a powerful antiphlogistic agent, and that the resulting inflammation and suppuration were much less than generally follow these injuries. The patient recovered.

Granted that a given supply of arterial blood is necessary to health, and that to repair an injury more than the usual quantity is requisite, one would expect either that repair would be slower after ligature than without it, or that the disease would degenerate from the acute to the chronic, or perhaps even to the ulcerative or gangrenous. And I am inclined to think that, in the case which was the origin of my operation and these remarks, the wound which opened the joint, as well as a small incision made subsequently over the inner side of the knee to give exit to supposed pus present there, healed more slowly than they would have done had not the vascular supply of the limb been interfered with. If I am correct in this opinion, questions arising out of it are, At what age and state of the constitution, and at what stage of the disease, is this method of treatment admissible? At present I am rather of opinion that the age and state of health of a patient (with special reference to his heart and arteries) who would have the barest prospect of recovery from an uncontrolled suppurative inflammation of the knee-joint would weigh with me against the use of the ligature, and I should try compression, either digital or instrumental. In all probability the injury would be fatal under any circumstances.

The stage of the disease at which ligature of the main vessel (femoral, for example) would be contra-indicated would appear to be, judging from very limited experience, the suppurative, but of long standing. This observation is supported by the progress of Mr. Reeves's case. The good effect of the ligature was very transient—a circumstance probably due to the high vascular condition of the part consequent on prolonged inflammation in it. On the other hand, judging from equally limited experience in the child, profuse suppuration of a more recent date may be arrested by the ligature. In the upper extremity, in which arterial anastomosis is more free and repair more readily effected, the brachial artery might be ligatured, at a more advanced stage of suppuration, with every prospect of success. In Cases 12, 15, and 17, instances of inflamed hand associated with extensive suppuration and some sloughing, a favourable change occurred directly after the application of the ligature to the brachial artery. The *precise* moment and *indication* for the application of the ligature in the lower extremity is when suppuration is only suspected to have occurred, or has only just set in.

When enumerating the risks inherent to the ligature, the possible ill-performance of the operation—a segment or whole of the vein being included in the ligature—ought not to be omitted.[*]

Time does not allow me to compare further the results of acute suppurative inflammation treated on the *ordinary* principles of surgery with the *extraordinary*, or ligature of the main artery. As I have said elsewhere, I believe the sudden obstruction of a main artery to be very much less dangerous than is generally supposed. We have been apt to draw our conclusions from instances of known diseased vessels, as in cases of aneurism. I was once present when a friend accidentally wounded the superficial femoral artery while opening an abscess in the thigh. We at once placed a ligature above and below the wound in the vessel, and no ill consequences whatever arose.

On Sept. 7th, 1867 (Case 10, Table of Arteries), I placed a double ligature upon the superficial femoral artery of a young man within an hour of its being wounded. He quickly recovered without the least sign of want of circulation in the foot. Again, in 1871 (Case 11), I ligatured the superficial femoral for a contused lacerated wound of the vessel. The man was of intemperate habits. Gangrene attacked the wound, and the man died ten days subsequently; but there was never the least evidence of insufficient supply of arterial blood to the foot.

These cases suffice to show how rapidly the collateral circulation is established, and the part does not perish. Wardrop,[†] also, says: "The enlargement of the anastomosing vessels to a certain extent takes place almost instantly after the trunk has been tied. I observed this in a child in whom I had secured the carotid artery. I could see the branches of the temporal and occipital underneath the delicate integument enlarging, and thus actively acquiring great additional vigour immediately after the operation."

---

[*] Plaies d'Armes à Feu, Paris, 1830; p. 262.

[*] Maunder's Operative Surgery, 1873, p. 87: "I have repeatedly seen the vein wounded by gentlemen attending my 'course of operations' in Paris."

[†] Wardrop on Aneurism, p. 12.

There is thus accumulated a fair amount of experience to show that the principle of *withholding* blood from an inflamed structure, under certain conditions, is immediately beneficial. As to the means to this end, let them be as innocent as may be consistent with success. I would not for a moment insist on the application of a ligature in all cases where the principle is to be tried, provided that a simpler method will suffice, whether by compression with a tourniquet, by acupressure needle, or by hand. But it must not be forgotten that it is one thing to suggest a mode of treatment and another thing to carry it out efficiently. The ligature once applied, all anxiety as regards the passage of blood ceases; but less decided measures above mentioned require such care and attention to details as can rarely be given. Having witnessed the value of the principle, I do not hesitate to urge upon the profession a trial of it when practicable. It may appear strange that I have not tied an artery oftener for inflammation; but I did not wish to ride my hobby to death, nor to bring the principle into discredit.

Facts and Conclusions.

That ligature of the superficial femoral artery has arrested acute inflammation consequent on wound of the knee-joint.

That ligature of a main artery will quickly diminish profuse suppuration, and prevent death by exhaustion.

That, while it arrests profuse suppuration, it will, by allowing the patient to gain strength, afford an opportunity for amputation at a future time.

That gangrene and secondary hæmorrhage, as the result of ligature, should not be anticipated in the healthy subject.

That the dread of these has arisen from our knowledge of the consequences of the ligature in instances of known diseased vessels—aneurism, for example.

That a slough on the heel, caused by the pressure of a splint, was quickly detached, and the wound soon closed, although the superficial femoral had been tied a few days previously.

That symptoms of inflamed bone "starting pains") quickly disappeared.

That the arterial tension of the rest of the body will be increased beneficially by the ligature.

Such, Mr. President, are the conclusions at which I have arrived from a review of the above subject; but seeing that this operation was originated in America long before I was born, while I thought it had been first suggested by me in 1866, I may well say "there is nothing new under the sun."

I have now come to the end of my Lettsomian Lectures, and, in doing so, beg once more to thank the Council of the Medical Society of London for having nominated me to the honourable office, and my audience for having listened patiently to my discourses.

ON THE CURE OF LEUKHÆMIA SPLENICA BY MEANS OF PHOSPHORUS.

By WILSON FOX, M.D., F.R.S.,
HOLME PROFESSOR OF CLINICAL MEDICINE, UNIV. COLL. LOND.

I desire to take an early opportunity of corroborating an observation by Dr. Broadbent* on the influence of phosphorus in this disease, and I hope that the experience of others may be found as favourable as his and my own have proved to be.

The patient, E. C. U——, a male, aged thirty-seven, was admitted into University College Hospital Dec. 30th, 1874. Born in Devonshire, he has resided for the last twelve years in London. By trade a baker; for eight years he worked in the bakehouse, for the past four he has been in the shop. He has never even stayed in a known malarial climate. His father lived to an advanced age; cause of death unknown. His mother before her death (age unknown) was very pallid, and suffered from severe pain in the "body" and shortness of breath. One sister living, aged forty, suffers from pain in the body and limbs, and from shortness of breath. Patient has been married nine years. Lost the only child born alive soon after its birth. His wife has had one miscarriage; no subsequent pregnancy.

Previous illnesses.—Has had scarlatina and measles, the latter severely; neither rheumatism nor syphilis. Some years ago, soon after joining the baking trade, he became very weak and ill, but recovered completely. Six years ago he became very blanched, owing to bleeding piles. He recovered completely from this, and though he states that he has occasionally observed himself looking yellow, yet up to his present illness he was a very strong, vigorous man, weighing 12 st. 6 lb., and able to lift and carry a sack of flour. Height, 5 ft. 6 in. His present illness commenced in January, 1873 (nearly two years before admission). First suffered from severe pain in his right side after lifting a heavy weight. He kept his bed a fortnight, and remained well for three months. He then began to feel a "dull, heavy" pain in his left side, which varied in intensity, but did not become severe until 1874. During this period, however, he noticed some enlargement of the abdomen. In 1874 he suffered from at least twelve attacks of very severe pain in the left side. They were preceded by feelings of chilliness, and were attended by night perspirations and by urine loaded with lithates. In October, 1874, he had an excessively severe attack of this nature, attended by violent vomiting. The pain extended to the hip and groin to such an extent as to give rise to the diagnosis of a renal calculus. The pain gradually diminished, but returned on the 21st of December, extending to the hip and knee. At this time he passed half an ounce of dark blood by the rectum. He had no other hæmorrhage. His breath had become short since October.

On admission he was intensely pallid, with extremely marked anæmia of the mucous surfaces and of the nails; markedly emaciated; no eruption of skin; very feeble, hardly able to stand without assistance; no œdema. He had frequent slight rigors; was pyrexial, and sweated profusely. The urine was high-coloured, sp. gr. varied from 1010 to 1025; it deposited lithates, but contained neither albumen nor sugar. The lungs were healthy. The heart's apex (displaced by the abdominal tumour) was in the fourth interspace; there was a faint basic systolic murmur with its maximum at the second left cartilage; venous hum was heard in the neck, and arterial murmurs were present.

His appetite was bad, his bowels were costive, though previously diarrhœa had alternated with the constipation; the stools presented no special abnormal appearance. He suffered much from flatulence. He had constant thirst; mouth dry, tongue broad, flabby, and covered with a thin white fur. The sight was unimpaired. He occasionally suffered from severe headache. Anæsthesia existed over the outer part of the left thigh. Some hyperæsthesia was also observed in the course of the last dorsal nerve.

The abdomen was distended chiefly in the left flank in the splenic region, where there was felt a hard resistant mass pushing outwards the cartilages of the tenth and eleventh ribs, and reaching backwards nearly to the spine, though the intestinal note could be elicited posteriorly between its posterior border and the spine. It was smooth, without any nodulation; movable from behind forwards, and movable on deep respiration. The anterior border was distinct, slightly rounded, and in its middle the splenic notch could be distinguished on deep pressure. The whole mass was absolutely dull on percussion, and without fluctuation. The dulness superiorly extended to the sixth rib in the axilla, between the eighth and ninth ribs in the back. By palpation and percussion the tumour was traced extending across the abdomen to within 1½ in. to 2 in. to the left of the umbilicus; thence it extended transversely backwards until it touched Poupart's ligament, about 1 in. anterior to the crest of the ilium, below which bone it passed posteriorly. The tumour was intensely painful on deep pressure. Between it and the diaphragm friction could be heard. The patient was unable to lie on his right side owing to the aggravation which this caused of the pain felt in the thigh and knee, and to pain in the left scapular region.

No enlarged veins were seen on the surface of the abdomen. There was no ascites. The liver was not enlarged. There was no enlargement of any of the superficial lymphatics, nor could any be felt in the abdomen, with the exception of a few slightly in excess of the normal size in the inguinal regions.

---

* Practitioner, Jan. 1875.

The blood[*] drawn by pricking the finger looked much paler than natural. The corpuscles were nearly twenty times their usual number, from thirty to forty-five being seen in the field. This proportion remained constant during the greater part if not the whole of the period before he began to take the phosphorus. The white corpuscles were of two kinds, large and small, the former about twice the natural size; some were binucleated; most were granular. There was, in addition, a large number of molecules, which were aggregated into irregular masses. There was no alteration in the shape or appearance of the red corpuscles.

Until Jan. 20th, when the treatment by phosphorus was commenced, his state varied but little. He had more or less continuous severe pain in the tumour, which at times was aggravated by sharp paroxysmal attacks, relieved occasionally by blisterings and endermic application of morphia, or by the hypodermic injection of morphia.

Until Jan. 20th he was almost constantly pyrexial, and slight febrile movements, not exceeding 99·9°, also occasionally persisted until Feb. 8th (nineteen days after the treatment by phosphorus had been commenced). On a few days the evening temperature was not taken. On three occasions only within the first twenty-one days the temperature during twenty-four hours did not exceed 98·5°. The pyrexia, prior to Jan. 20th, was irregular in its diurnal manifestations. The maximum observed was 101·2°, and it tended to a post-meridial exacerbation, the morning temperatures being normal, but never subnormal. This regular course was, however, only maintained on six out of twenty days, and many variations occurred; thus, in some instances, ante-meridial pyrexia was observed, sometimes equalling, in others less than that of the evening. On other days the evening temperature being high, continued so through the early part of the night. The temperature was also observed to be high in the morning, to fall towards midday, and rise again in the evening. After Jan. 11th and before the phosphorus was given, the temperature did not exceed 99·9°.

The pulse up to Jan. 20th varied from 96 to 132, only once falling to 88; the respiration varied from 16 to 22.

Before the date at which the phosphorus was first given the treatment consisted of the administration of iodide of iron. Sulpho-carbolate of soda was also given with some relief for the flatulence. Full diet, wine, and lemons were also given.

Until this date no material improvement had taken place in the general condition of the patient. He was still febrile, though slightly less so than on admission; his blood was in about the same state, and the attacks of pain in the region of the splenic tumour were severe. Having just met with Dr. Broadbent's paper, I determined to try the effect of phosphorus, and ordered one-fiftieth of a grain three times a day, which on Feb. 23rd was increased to one-thirtieth of a grain three times a day. All other treatment beyond rest and nourishing food was discontinued. No ill effects were observed from the phosphorus throughout. At first but little appreciable influence was noticed on his general condition, except that the pulse had diminished in frequency, varying up to Feb. 8th from 88 to 96, after which it gradually fell, rarely ever reaching 90, and varying from 76 to 62. The pyrexia also, as before stated, subsided, and after Feb. 8th it only reached 99° on two occasions (Feb. 25th and March 5th). Subnormal temperatures, occurring almost exclusively in the morning, but not falling below 97°, were occasional throughout the months of February and March, but almost ceased, though not entirely, during the month of April. On the 25th March he contracted a bronchial catarrh without any pyrexia, which only lasted a few days, and was not treated except by a few doses of chloral hydrate at night, to allay cough.

By the 8th Feb. there was a marked improvement in the appetite, which continued, and the bowels became regular.

By the early part of March the aspect of the patient had begun to improve, and on March 2nd examination of the blood with the microscope showed only about eight white corpuscles in the field of a quarter of an inch, still being divisible into those of large and small-sized, besides a number of molecules.

By March 14th he could walk with help.

By April 6th he was much better; the anæmic look had disappeared, and there was some diminution in the size of the spleen, which no longer passed below the crest of the ilium, while the dulness superiorly reached to the eighth interspace in the axilla.

April 9th.—Five to nine white corpuscles were seen in the field of the microscope.

20th.—They had diminished to five or seven.

May 5th.—There was no apparent excess whatever of the white corpuscles. The patient was able to walk a mile without fatigue. The anterior border of the spleen, instead of reaching nearly to the umbilicus, was five inches to the left of the middle line, and about two fingers' breadth from the crest of the ilium, while the dulness superiorly only reached the seventh rib in the axilla. It was no longer painful.

On the 7th he was discharged for Eastbourne, discontinuing medicine; and in June he returned, looking the picture of health, but without any further appreciable diminution of the size of the spleen. His blood, tested against that of a healthy man, showed no increase of the white corpuscles, but these were nearly double the natural size.[*]

I subjoin his weighings during the latter part of his treatment by phosphorus. I very much regret that these were not ascertained during the first part of his stay in the hospital:—Weight two years ago in perfect health,[†] 159 and 174 lb.; March 12th, 124 lb.; 22nd, 127 lb.; 30th, 130 lb.; April 6th, 132 lb.; 16th, 133½ lb.; 23rd, 135 lb.; 29th, 140 lb.; May 6th, 142 lb.; middle of June, having returned from Eastbourne, 147 lb.

Remarks.—It hardly appears necessary to comment on the diagnosis of this case as being one of genuine leukhæmia. The change in the blood was certainly not so far advanced as is sometimes observed, when the white corpuscles may be to the red as 2 : 3. This condition is, however, only noticed as a rule in the final stages of the disease, and even in these the proportion of white to red may by no means be excessive, and, as I have myself observed, they may even diminish from the amount seen in the earlier periods. It appears, also, from Mosler's[‡] observations, that splenic enlargement may exist during a considerable period before any marked increase of the white corpuscles is perceptible, during which time other characteristic symptoms of the disease may nevertheless be present, and also that as many as sixteen corpuscles counted in the field may, together with splenic enlargement and slight pyrexia, be sufficient to characterise the disease. Dr. Broadbent doubted whether the case observed by him was an absolutely characteristic one of leukhæmia, on account of the want of correspondence between the degree of anæmia observed and the number of white corpuscles found. I am disposed, however, to believe from observations on other cases, that this want of correspondence is not unfrequent in true leukhæmia, and that the red corpuscles suffer in their nutrition in this disease as well as in the anæmia splenica or lymphatica of Hodgkin,[§] from which a moderate excess of white corpuscles in the blood is sufficient to distinguish it. In this case, however, the increase in their number was sufficiently great fully to characterise the disease. The absence of the severer hæmorrhagic symptoms was certainly a point in the patient's favour; but in other respects, as regards his emaciation and great loss of strength, his prospects were most unfavourable; and before the good effects of the phosphorus were observed I only anticipated for him the melancholy and painful termination which is almost constantly, if not invariably, observed in this disease. I say almost constantly because Mosler anticipates for quinine, if used in the earlier stages, a somewhat hopeful influence on the cure of leukhæmia, and has quoted four cases of cure by this agent; I must, however, confess that even in very large doses, of ten to twenty grains daily, continued during a long period, quinine has always failed in my hands to exercise the slightest influence, either on the fatal progress of the disease or on the pyrexia. Iron also has appeared to me to be equally inefficacious, and the experience of the majority of observers seems to have been as unfavourable as my own.*

---

[*] The report on the blood is the result of my own observations, collated with those made within the first three weeks after admission by Messrs. Rogers and Voelcker, Fellowes clinical prize essayists. I am also indebted to the latter gentleman for a few addenda to the general history.

[*] Observation by my clinical assistant, Mr. Pepper.

[†] Differently stated by patient.

[‡] Pathologie et Therapie du Leukhæmie. Berlin, 1872.

[§] See Dr. Wilks, Guy's Hospital Reports, 1856.

It may be noticed that neither in Dr. Broadbent's case nor in mine did the spleen return to its natural size, though in mine there has been a not inconsiderable diminution of its dimensions. Dr. Broadbent is indeed under some fears, owing to not hearing again from his patient, that some unfavourable change may have taken place in his state. It is impossible as yet to speculate what effect the still enlarged spleen may have on the general health, but the hope that this may be slight or *nil* does not appear to me to be ill-founded. In the cases of cure reported by Mosler under the influence of quinine, the spleen is stated to have returned to its normal dimensions; but one of these, by Dr. Hewson, of Pennsylvania, was distinctly a case of malarial origin, in which paroxysms of intermittent fever still persisted, and in which the administration of the quinine appeared to exert a beneficial effect, while in the others the splenic enlargement was less than in the present instance.

As far as is yet known, no case of spontaneous cure of leukhæmia has been reported, or of recovery under indifferent treatment.† The fact that some amelioration had from time to time taken place in this patient's state during the earlier period of his illness affords no ground for the belief that this explanation is valid for the rapid improvement observed after he had commenced to take the phosphorus. Such alternations of improvement and exacerbation are common during the early periods; but when once the splenic tumour has attained a considerable size and the increase of the white corpuscles in the blood is marked, any change for the better, except slight and transient modifications of the pyrexia, are rarely observed.

I believe, therefore, that in this case, as well as in Dr. Broadbent's, the cure is exclusively attributable to the use of the phosphorus, and he is warmly to be congratulated on the successful verification of an induction, and on the discovery of a cure for at least some cases of a disease so painful, distressing, and hopeless as this almost invariably proves to be. It may be found to be more beneficial in the earlier rather than in the later stages of the disease. What its influence may be when the vast excess of white corpuscles sometimes observed has been attained, can only be verified by further observation, but I trust that it will soon receive a more extended trial in all phases of the disorder, and that it may be shown that one more disease has been thus rescued from the category of the almost hopelessly irremediable.

In conclusion, I would allude to the observations by Prof. Botkin, of St. Petersburg,‡ on the reduction capable of being effected in the size of the spleen and lymphatic glands, and also of the proportion of the white corpuscles in the blood, by the application of the induced current to the enlarged spleen and glands. These are very distinct and remarkable, and may yet prove to be an important adjuvant to treatment. In this case I was, however, desirous to give the phosphorus an uncomplicated trial, and did not, therefore, adopt Prof. Botkin's method.

---

* A remarkable case is reported by Dr. Lloyd Roberts (Brit. Med. Jour., 1869, ii., 585), where, in a case of great anæmia, the white corpuscles were increased in the proportion of one to two of the red, without any enlargement of the spleen or of the lymphatic glands, and where in the course of fifteen days the excess of white corpuscles had almost entirely disappeared. This case, as far as I know, is quite unique, and cannot be considered one of true leukhæmia.

† One is alluded to by Dr. Willoughby Wade (Brit. Med. Journ., 1869, ii., 644), in an infant fifteen months old, where a splenic tumour disappeared within fifteen months; but no other details are given respecting the state of the blood or the treatment adopted.

‡ Die Contraktilität der Miltz. Berlin, 1874.

DR. PETER, of St. Antoine Hospital, mentions having seen the use of a bath produce most mischievous effects in pelvi-peritonitis. He explains the fact in the following way:—On entering the bath, and in order to stride over the edge of it, the woman makes a violent movement, which destroys some of the adhesions established around the internal genital organs, and this rupture becomes the starting-point of a new onset of peritonitis.

HEALING OF WOUNDS BY BLOOD-TISSUE.

BY JOHN CHIENE,
ASSISTANT-SURGEON, EDINBURGH ROYAL INFIRMARY.

> "The blood being alive, this uniting medium becomes immediately a part of ourselves, and the parts not being offended by it, no irritation is produced."—JOHN HUNTER (chapter on Union by the First Intention).

THE organisation of an accidental blood-clot in open antiseptic wounds in Mr. Lister's practice and in cases under my own care, first suggested to my mind the propriety of trying to heal a recent open wound by filling, at the time of the operation, the cavity with blood, which would coagulate, become organised, and which in time would become covered with epithelium. The expectation was that less contraction would follow if the wound healed by blood-tissue than if it was allowed to granulate and heal by cicatrisation.

A young man suffering from a horn on the point of the heel was admitted into the surgical clinical wards in the Edinburgh Royal Infirmary in April last. The case appeared a suitable one for the experiment, because the situation and nature of the wound which would require to be made in order to remove the horny projection was such that union by the first intention was unattainable, and if the wound was allowed to granulate and heal by cicatrisation and contraction, like an ulcer, the result would be drawing up of the heel and deformity and lameness in walking. The horn had been removed twice previously, but had again grown. At one of these operations the healing of the wound was assisted by the organisation of an accidental blood-clot. The horn now projected from the surface to the extent of the third of an inch, consisting of layers of horny epithelium, and had a circular base nearly the size of a shilling.

On the 18th of April, 1875, a tourniquet was applied, and the horn removed; the resulting wound was triangular in shape, each side of the triangle being an inch and a quarter in length. The soft tissues down to the bone were removed, and the surface of the os calcis scraped with a periosteum scraper. The cavity was half an inch in depth. No vessels were tied. A piece of protective was placed over the opening in order to close it, and the usual antiseptic dressing applied. The tourniquet was then removed. The expectation was that blood pouring from the sides and floor would fill the cavity. The operation was performed under a spray of carbolic acid. On the following day the wound was dressed, and it was found that, with the exception of a shallow depression at one corner, the entire cavity was filled with dark clot. This was not disturbed, and the dressing carefully reapplied. On the sixth day the clot was of jelly-like consistence, and still of a dark colour. On the twelfth day the clot was of firmer consistence, and of a dark-brown colour. The clot did not bleed when scratched. On the sixteenth day the superficial portion of the clot, which corresponded to the depth of the thickened horny epithelium of the heel, liquefied, and came away in the discharges. The surface of the clot was now on a level with the deepest layer of horny epithelium. It bled when scratched at its centre, and the escaping blood filled a slight groove on the surface of the original clot. On the twenty-sixth day the original clot was distinctly vascular, and on its surface the secondary clot (the result of the scratching of the original clot on the sixteenth day) was observed of a dark colour, and adherent to the original clot. This secondary clot passed through the same changes as the original clot; the changes were, however, more rapid, in consequence, I presume, of its smaller size. On the thirtieth day the sharp-defined edges of the original wound in the horny epithelium had disappeared, and an epidermic formation was observed on the surface of the clot at its edges. On the thirty-fourth day the wound was healed, the blood-clot being entirely covered with epithelium. The triangular wound was still distinctly marked, and no contraction had taken place. No attempt was made by bandaging or splints to prevent contraction during the cure.

The patient was shown at the June meeting of the Medico-Chirurgical Society of this city. It has yet to be seen whether contraction will take place. The practical value of this method of healing wounds by blood-tissue has yet to be tested by further experiment. The case is, however, worthy of record: first, because, as far as I am aware, it is the first in which a systematic attempt has been made to utilise blood as a tissue for the filling up of an open wound. At present it seems to verify the quotation from John Hunter with which this short paper is headed. Secondly, because it is a practical lesson, teaching the slight amount of irritation in wounds treated antiseptically; it is a visible picture of the unseen changes which take place in a subcutaneous blood-clot as in a simple fracture.

Edinburgh.

NOTE ON

DR. HARVEY'S COMMUNICATION "ON THE PHYSICAL CAUSE OF THE PRESYSTOLIC MURMUR."

By W. T. GAIRDNER, M.D.

Had the recent paper of Dr. Harvey,* under the title given above, been less pointedly directed to the refutation of what I have published on the subject to which it refers, I should probably have waited until my own engagements and the less crowded state of the columns of The Lancet allowed of a reply more at length, and less controversial in form, than the present. But, with every possible respect for the high character and just reputation of my friend's many and valuable contributions to physiology and pathology, I must be allowed to say that I think the answer (so far as immediately required) to his present questioning lies in a nutshell, and I will therefore ask for so much space as will admit of this brief rejoinder.

In the first place, it appears that Dr. Harvey's doubts (as expressed in the second paragraph) extend considerably beyond the question raised by the title of his paper; for, not content with a statement of difficulties as to the *physical cause* of the presystolic murmur, he frankly confesses that he has never been able to hear the murmur itself, even in cases in which others have heard it. Not being able, therefore, either personally to verify the facts as stated by me, or to accept the explanation given, Dr. Harvey has, not unnaturally, been led to discredit the murmur altogether. It would certainly be vain to attempt to satisfy him as to the physical cause of a phenomenon of whose very existence he remains, after many years of investigation, still a little more than doubtful. I am almost astonished that he did not, under the circumstances, dismiss the inquiry into the cause of the presystolic murmur as irrelevant, and confine the scope of his paper to the discussion of the fact. For by raising hypothetical difficulties about the theoretical interpretation of the facts stated by me he certainly makes it appear as though the very existence of the murmur were as hypothetical and as much in dispute as the interpretation of it.

Now, in everything that I have written upon the subject of what I have called the *auricular-systolic* murmur, I have at least intended that it should appear clearly as a matter not of belief nor of theory, but of most positive and direct observation, that a murmur *distinctively preceding and running sharply up to the first sound of the heart* may, in certain cases, be easily verified, and distinguished from all other endocardial murmurs. Further, that the murmur of which the above is the most characteristic expression is often associated with murmur, of more or less intensity, *extending from the second sound through the pause*, but still subordinate in its importance to the auricular-systolic murmur as above described. Further, that all the murmurs now indicated, and especially the auricular-systolic, which gives the character and significance to the others, have been, by steady continuous observation over a long series of years, shown to be present—then and then only—when there are organic changes in the endocardium appreciably obstructing the flow of blood through the auriculo-ventricular orifices.†

I would earnestly beg my friend Dr. Harvey, and with him all others who may be disposed to write about these murmurs in the way of controverting or impugning what I have written, to do me the favour to discuss these points, in the first instance at least, as questions of fact, and not of hypothesis. If the statements above briefly given are not statements of fact and of direct clinical observation, we need not be at the trouble to find a theory or a *rationale* of them; we may simply say, *cadit quæstio*. But if these statements, considered simply from the point of view of experience, are true; if they are real and accurate expressions of what has been actually observed,—then it is vain to attempt to overthrow or to discredit them by reasonings such as those which constitute the bulk of Dr. Harvey's paper.

Now, I contend that these statements are, every one of them, and all of them together, the simple and absolutely unqualified expression of facts observed by myself and others, not in one or two, but in scores, or perhaps hundreds, of cases, many of them tested and completed by post-mortem examination.

When I have said thus much I by no means wish to deny that the observation of the murmur in question derives great additional interest from the reasonings that naturally arise as to its causation; but I do most earnestly protest against these reasonings being placed in advance of the determination of the objective facts—which, apart from any reasonings at all, are to me as nearly as possible absolutely certain; being the result of multiplied observations, secured in every possible way against fallacy. Dr. Harvey has in his paper endeavoured to raise a presumption against my statements, on the ground that, from his point of view, these statements *ought* not to be true; my answer is that these statements *are* true, and that in any reasoning on the subject we must first have determined by observation whether they are so or not. I cannot allow the auricular-systolic murmur, which I regard as a clearly ascertained and demonstrated clinical fact, to be caught up in a mere sidewind of doubtful doctrine as to the assumed power, or want of power, of the auricular contractions to produce such a murmur. I believe, indeed, that Dr. Harvey greatly undervalues the importance, and also the completeness and force, of the auricular contractions; but it is to be observed that, in calling this murmur auricular-systolic, I have not even affirmed that it is *due* to the auricular systole, but only that it *concurs in point of time with it*; just as the ventricular-diastolic murmur is so named from its coinciding with the ventricular diastole, although its actual cause is usually the recoil of the blood in the aorta upon the incompetent sigmoid valves. That the murmur is, in rhythm and in fact, auricular-systolic, is admitted by all, or almost all, those who have recognised it as presystolic—by such observers, for example, as Dr. Peacock (who at first had difficulties in recognising the murmur, but now affirms in every point the facts as above stated), Dr. Walshe, Dr. Hilton Fagge, and Dr. George Balfour.

Such being the state of the question of fact, is it too much to infer that Dr. Harvey, in putting together his reasonings and assumptions as to the degree of force and effectiveness of the auricular contraction, ought to have given increased attention to the established and well-known characters of the murmur, instead of making his preconceived notions on this subject a ground for discrediting the existence of the murmur? Such, I am persuaded, will be the opinion of most of those who have personally ascertained and studied for themselves the murmur in question. What we have to deal with, in any theoretical inquiry into the subject, is *a murmur of variable intensity and prolongation, which occurs while the ventricle is filling, and is characteristically rough and loud just before the ventricular systole*—i. e., during the period that physiology assigns to the contraction of the auricles. Whether the auricular systole is forcible or feeble, complete or incomplete, expelling a few drops only or a considerable current of blood, are questions fairly to be entertained, and of no small physiological interest; but, from the clinical point of view, I have to urge that these questions must in any case be so entertained as not to set aside or to discredit the facts above mentioned, but rather to include and comprehend them. And at this point I leave the discussion for the present, to resume it ere long, I trust, in a less controversial attitude. I would, in the meantime, recommend to Dr. Harvey's serious attention the admirable article by Dr. Galabin, in the recently published number of Guy's Hospital Reports. Indeed, I am satisfied that the more this curious murmur is studied, the more will it throw light upon some of the obscurest points in cardiac physiology and pathology.

Glasgow.

INTERESTING CASE OF INJURY OF THE SACRO-ILIAC JOINT OCCURRING IN A CHILD FOUR YEARS OLD.*

By JOHN FAGAN, F.R.C.S.I.,
SURGEON TO THE BELFAST HOSPITAL FOR SICK CHILDREN.

Eleanor D——, aged four years, was admitted, under my care, into the Children's Hospital, on February 4th, 1875. She presented a most wretched, wan, and pinched appearance; her countenance wore the characteristic expression seen in a child that is exhausted with intense suffering. On examination, I found the left gluteal and sacral regions enormously swollen and of a dark purple colour, the integument tense and glistening, and large tortuous veins ramifying through it. There was well-marked fluctuation in it, and at one place the skin seemed on the point of breaking.

The history I got from the mother was as follows. About three weeks previous to her admission the child was in perfect health, till one day, standing on a stool placed on top of a box, the lid being old, it gave way, and she fell through with the stool into the box, sustaining an injury somewhere about the hip. The medical man who was treating the case thought it to be one of hip disease, and, seeing it assume the very serious character it did, recommended the mother to take it to the hospital.

The treatment I employed in this case was as follows. After giving the child some wine, I introduced the needle of the aspirator into the abscess where the skin was soundest, and drew off about fourteen ounces of thin unhealthy pus; this relieved the tension very much, and I should say removed about half the quantity of fluid from the sac. The child was then put to bed, and got for nourishment six ounces of wine, an ounce of brandy, two eggs, and milk *ad libitum* in the twenty-four hours. The next day I again used the aspirator, and removed nearly as much pus of the same character as the day before. The nurse drew my attention at this stage to a small lump in the groin, which looked and felt somewhat like an enlarged gland. In a few days this got much larger, and conveyed a distinct sense of fluctuation. The use of the aspirator on two occasions, taking away about three ounces of pus the first time and an ounce and a half the next, completely removed the swelling. On the 24th of February, just twenty days after her admission, I required to use the aspirator for the last time. For several days previous to this the swelling in the groin had disappeared, and that over the sacrum was getting less. In all I used the aspirator nine times, and removed about sixty ounces of pus. After emptying the abscess on the three or four last occasions, the walls of the sac collapsed, leaving a deep sulcus between the prominent spinous processes of the sacrum and posterior border of the ilium. This I padded with cotton-wool, and used slight pressure by means of strips of adhesive plaster and a bandage round the pelvis. On the 8th of March the child was sent home quite plump and fat, and able to trot about without the slightest indication of lameness.

This case I consider interesting from a threefold point of view: its diagnosis, prognosis, and treatment. Acute inflammation of the sacro-iliac joint is, I believe, a very rare affection, probably due to the fact that its position in the body renders it less liable to be exposed to the many causes that give rise to inflammation in other joints, as also to the fact that it is the nearest approach to an immovable joint. That it is more likely to occur in childhood is owing no doubt to this joint possessing a delicate synovial membrane during that period, and consequently apt to take on inflammatory action when subjected to any undue violence. That the suppuration about the joint was the result of the injury sustained by the child when she fell through the box there can be no doubt, but the exact nature of the affection was a very puzzling point to make sure about, at least when first I saw the child. As I pointed out to some students who were present when the child was admitted, there were symptoms about the case that would warrant one in diagnosing it as a case where the hip-joint or sacro-iliac joint was engaged, or a severe contusion of the muscular structure about these parts, or a combination of all three. Although the case was treated by a medical man as one of hip-joint disease (according to the mother's statement) there were but very few symptoms pointing to that condition, and those of a character that might arise from other causes. The thigh was flexed on the pelvis and adducted, and there was great pain on attempting to rotate the limb—symptoms likely to be present in disease of either of the joints; while the position of the abscess, the rapid course of the affection, and most particularly the absence of pain when the great trochanter was pressed upon, gave the strongest presumptive evidence that the hip-joint was not the seat of lesion in this case.

The opinion I expressed at the time was, that it was a large abscess resulting from a severe contusion of the muscular structure, and as the child suffered great pain when the sacrum or ilium was pressed upon, that probably there was some inflammation of the sacro-iliac joint. A few days afterwards the appearance of the swelling in the groin confirmed my diagnosis. The matter made its way from the joint under the iliac fascia, and, following the course of the iliacus muscle, made its appearance at the site usually occupied by a psoas abscess.

As regards prognosis, I was at first disposed to give a most unfavourable one, and would look on the case as hopeless but that I had great faith in the recuperative powers of children when placed under favourable conditions. The rapidity and completeness of the cure in this instance would dispose me to give a favourable prognosis in cases of an acute character, with some reservation, however, as all such might not be expected to terminate in so satisfactory a manner as the one under consideration. I have met with cases of disease of this joint occurring in ill-conditioned strumous children, some of which I have under my observation at present, and hope to give the history of them at some future time. The prognosis in their case must naturally be of the most gloomy character.

The treatment I employed was rest, stimulants, light nutritious food, and the use of the aspirator. Of the latter instrument I cannot speak too highly. In cases such as the one I have just described it is invaluable. I have now been in the habit of using it constantly for the past three years, and can safely say that it has never done any harm; that it may occasionally disappoint one, but that in the majority of suitable cases it is the only instrument a surgeon should use who studies the well-being of his patient, as well as his own comfort.

CASE OF PULMONARY COLLAPSE CAUSED BY HÆMOPTYSIS; DIFFICULTY OF DIAGNOSIS.

By MARK LONG, M.D.

Feb. 17th, 1875.—Late last night, my partner, Dr. Gibbings, saw for me Miss G——, who had expectorated a large quantity of florid blood. She is twenty years of age, well nourished, robust-looking, and of rather florid complexion. She has had no cough or other illness, nor has she lost flesh recently. Indeed she has not needed medical advice since she first came under my care about two years ago. She was then suffering from debility and shortness of breath, which I found to be due to valvular cardiac disease. Her last illness before this was about three years previously, when she had a severe attack of typhoid fever. There is no trace of consumption on either her father's or mother's side. I found her to-day looking anxious and depressed, and still bringing up small quantities of bright blood, with a slight but frequent cough. She is taking a mixture containing liquid extract of ergot and gallic acid, ice, and cold fluid nourishment. The old loud presystolic murmur is audible over the greater part of the left side of the chest, and large crepitation is heard in both lungs anteriorly.

---

* Read before the Ulster Medical Society.

March 2nd. — The hæmorrhage gradually subsided, and had for some time quite disappeared, until last night, when, after a violent fit of coughing, she brought up about eight ounces of blood.

3rd.—Small quantities of florid blood are expectorated each time she coughs. Pulse 100. Heart's action rather tumultuous. Ordered a belladonna plaster.

4th.—The blood now brought up is rather darker, but still bright. Pulse 96. Heart's action rather quieter. On inspecting the chest, a distinct sinking is apparent under the left clavicle; all the upper part of the left lung is absolutely dull on percussion, and is nearly motionless on the fullest inspiration, in marked contrast to the right side, which is quite resonant and expands freely. No respiratory murmur can be heard in the supra- or infra-clavicular region on the left side, but loud bronchial breathing is audible in one spot to the left of the sternum in the infra-clavicular region. Dr. Munk saw the case with me to-day in consultation, and fully confirmed the presence of the above symptoms. He suggested the administration of five minims of tincture of digitalis and ten minims of the liquid extract of ergot, three times a day.

5th.—No alteration in the physical signs. Pulse 100; temperature 99·8°.

6th.—Brought up some very dark blood this morning. Dulness unaltered; no vesicular murmur; slight expansion on inspiration.

7th.—Dulness not so absolute; slight respiratory murmur; expectorated more dark blood.

8th.—Vesicular murmur rapidly increasing, and dulness diminishing; more dark blood brought up.

19th.—Since last date the patient has steadily improved, and there is now no infra-clavicular sinking, and no difference can be detected between the right and left apices with regard to percussion note, vesicular murmur, or expansion during inspiration.

Remarks.—This case was a most interesting one from a diagnostic point of view, and also with regard to prognosis, as the patient's friends were most anxious for a positive opinion as to the presence of lung disease, and Dr. Munk and myself could not venture to give more than a guarded one. All the local physical signs of phthisical consolidation were present, and, upon any other supposition, it was difficult to account for them all, especially the infra-clavicular sinking, which was very marked; but considering the very good family history of the patient, and her condition for some time previous to the attack, I formed the opinion that there must be some other explanation. Pneumonia would have accounted for all the other signs, but not for the infra-clavicular depression; the same may be said of "pulmonary apoplexy." I was therefore led to the conclusion that most probably collapse of the upper part of the lung had been caused by the frequent expirations of a violent fit of coughing nearly emptying the pulmonary air-vesicles, and by a sudden inspiration then sucking a quantity of blood or perhaps a clot into the main bronchus, and thus shutting off the air from the vesicles beyond it. Such an occurrence would account not only for all the signs due to consolidation, but also for the sinking of the thoracic wall, which was of course more evident from its proximity to the unyielding clavicle. I think the progress of the case proves the correctness of this opinion, as the abnormal physical signs gradually disappeared according as clots of dark blood were expectorated.

The above case seems to me to be worth publishing, first on account of its diagnostic interest, and, secondly, because I have not found hæmoptysis mentioned as even a possible cause of pulmonary collapse in any of the books I have at hand, and I have consulted Aitken, Tanner, Watson, Walshe, and Niemeyer.

Amhurst-road, Hackney.

Vivisection.—The Royal Commission on Vivisection held a preliminary meeting in one of the Committee-rooms of the House of Lords on Wednesday. There were present:—Viscount Cardwell (chairman), Lord Winmarleigh, Mr. W. E. Forster, Sir John Karslake, Mr. J. E. Erichsen, Mr. R. H. Hutton, and the secretary, Mr. N. Baker.

UNIVERSITY COLLEGE HOSPITAL.

TWO CASES OF SLOUGHING OF ARTERIES.

(Under the care of Mr. Heath.)

Though the two following cases—for the notes of which we are indebted to Mr. J. R. Godlee, surgical registrar—both terminated fatally, they have one point in common which is of some rarity and interest, and worthy to be placed on record. In both instances considerable sloughing of the principal artery of the limb took place, leading to secondary hæmorrhage; but in neither case was the bleeding so great as to be the immediate cause of death, and in the first case the hæmorrhage occurred only once, sixteen days before death.

J. B——, a woman aged twenty-eight, was admitted on Feb. 3rd, 1875, with a small cystic tumour on the outer side of the leg, three inches below the knee-joint. It was first noticed a year before, and had on one occasion been emptied by an aspirator, when a transparent sticky fluid escaped. The cyst was removed by Mr. Heath on Feb. 24th, when it was found to have a very thin wall, and to contain a glairy, clear fluid, closely resembling that which forms the contents of an ordinary ganglion. No difficulty was experienced in the operation, the connexion between the walls of the cyst and the surrounding tissues being at no part at all firm. Silver sutures were placed in the wound and a dry dressing applied, but in three days (Feb. 27th), after a slight rigor, the temperature had risen to 103·4°, and an angry blush, accompanied by great œdema, occupied the leg, while the glands in the groin became enlarged and painful. The pain was most severe around the knee-joint, especially on the inner side and in the popliteal space; but though a considerable amount of fluid occupied the joint at one time, none could be discovered in the first few days. By the 18th of March the sense of fluctuation in the knee-joint itself was no longer perceptible; but it became clear, as indeed had been suspected for some time, that there was a collection of matter at the inner part of the thigh. About two ounces of pus were removed with the aspirator, and on the 20th of March a free incision on the outer side of the limb gave vent to about four ounces of dark pus, and showed that there was an extensive abscess beneath the muscles surrounding the bone. The temperature had up to this time kept at about 101°, and the patient was already much exhausted. After the opening of the abscess the discharge became very profuse, and the weakness of the patient increased proportionately; she assumed a sallow and careworn appearance, was unable to take her food, and emaciated rapidly. The temperature varied from 98° to 103°, but was often high. On the 26th of April death occurred; but before this three important facts had been observed. On the 25th of March it was noticed that on holding up the limb by the heel great distortion occurred at the knee, and that the leg could in fact be bent at a very considerable angle with the thigh either forwards or laterally; on April 10th very copious hæmorrhage took place from the incision, which appeared to be arterial, and was stopped by a solution of perchloride of iron; and lastly, on April 20th, it was noticed that several of the toes were becoming gangrenous, and that no pulse could be felt either in the anterior or posterior tibial artery.

At the post-mortem examination the knee-joint was found to be completely disorganised, and to communicate by several openings with the large abscess in the thigh, which burrowed beneath the muscles in all directions, and joined the incision made in the removal of the tumour. The tibio-fibular articulation, though much inflamed, did not appear to be opened. The popliteal artery lay exposed in the abscess behind the knee, and, owing to the deformity of the joint, it lay over the most prominent part of the internal condyle. At this point its anterior wall had been completely eroded for a full inch. The deficiency extended up to within one-eighth of an inch of a large branch on the inner side, and this one-eighth of an inch of the main vessel was plugged by a minute clot, which was all that for 16 days had prevented hæmorrhage from occurring from this vessel. Below the erosion the lining membrane of the artery was much thickened, and the vessel was occupied by a very soft, breaking-down clot, nearly an inch long. The examination revealed no other points of interest beyond pneumonia and pleurisy on the right side.

The second case is that of an engine-driver, above the middle height, and of remarkably healthy appearance and good muscular development, who had suffered from a very chronic disease of the elbow-joint, with sinuses, which had apparently resulted from a blow received in following his occupation. The history of the illness may be thus briefly summed up:—Pain and swelling for eight months, with applications of iodine externally *secundum artem*; manipulation of the joint by a bone-setter without any improvement; continuation of his occupation for nearly two years, at the end of which time abscesses formed; then followed a period of eight months during which he suffered twice from erysipelas and was unable to work at all. At the end of this time, when he was admitted into the hospital, March 11, 1875, there was almost complete anchylosis, the movements of flexion and extension being only possible through an angle of 2° or 3°, and pronation and supination being altogether lost. The movements, as far as they were possible, caused no pain, and when completed a dead lock seemed to be arrived at. The joint was enlarged but free from heat, and there was much wasting of the limb.

On March 17th Mr. Heath forcibly flexed and extended the elbow, with the result of breaking down many adhesions and restoring a considerable amount of mobility. The immediate result, however, was the lighting up of a very sharp attack of inflammation in the limb, with great swelling and redness, possibly of an erysipelatous character, which resulted in the formation of several abscesses round the joint, requiring incision. The limb in the meantime was kept upon a hinged splint, and passive motion was practised at intervals. The result, however, was not satisfactory, and accordingly, on April 21st, Mr. Heath excised the joint. The operation was an exceedingly difficult one, partly on account of the rigidity of the soft parts outside the joint, but chiefly from the irregular enlargement of the ends of the bones from osteophytic growths. After removal, the bones were found to be covered with a thin layer of feeble granulations; the caries was quite superficial, but the articular ends were extremely dense. The wound was washed with a solution of chloride of zinc and stuffed with cotton wool, and the limb was placed upon a "Mason's" splint.

During the manipulations at the time of the excision a small rent had occurred in the skin over the front of the joint, and on April 26th, or 50 days afterwards, secondary hæmorrhage, considerable in amount, came from this opening, a little appearing at the same time from the excision wound. This recurred three times on April 28th, and, as it seemed probable that it was coming from the brachial, Mr. Heath enlarged the wound in the front of the joint, and tied the vessel, as was thought, above and below the point from which hæmorrhage was occurring. On April 30th, however, the bleeding recurred, and accordingly Mr. Heath enlarged the wound again, and tied the brachial artery just below the middle of the arm; but though the bleeding stopped for the time it again recurred on May 2nd, and on this occasion Mr. Heath amputated the arm in the middle third; the patient, however, who had been much reduced by the loss of blood, never rallied, but sank in the course of a few hours.

Some days before death pleurisy on the left side was diagnosed.

At the post-mortem examination the condition of the brachial artery was remarkable. The body was very anæmic. The vessels in the amputated limb were first examined, and were found to be normal in position and size. Of the two ligatures first applied, the lower surrounded the artery, but the upper enclosed a mass of sloughy connective tissue on the anterior surface of the vessel, and so had drawn considerably nearer the lower ligature than it had been previously. At two points—one immediately above the lower ligature and one a little above the upper—the front of the artery was grey and sloughy, but no actual hole in it could be discovered; no large branch came off in the immediate vicinity of these ligatures. Just below the lower ligature the anterior wall of the artery had completely disappeared by sloughing for about an inch, at the lower part of which space the vessel bifurcated, so that the mouths of the radial and ulnar arteries practically opened into a sinus which led up to the wound by the side of the artery. The interosseous and the smaller arteries about the joint came off quite naturally. There were no clots in the brachial vein, which was healthy. The third ligature was fairly round the artery, and immediately below it the anastomotic branch came off. The inferior profunda paired with the ulnar nerve as usual. The vessel which looked like a second brachial during the amputation was a contracted but large vein. The wound in the front of the arm communicated by a narrow sinus with the excision wound.

The following explanation of the events described in the notes is suggested:—1. The bleeding probably always came from below the point of the lowest ligature, but was directed up to a point opposite the interval between the first two ligatures by the comparatively small sinus into which the ruptured vessel opened. 2. After the first ligature was applied, recurrent circulation would be supplied by all the anastomoses round the elbow not interfered with by the operation of excision; and, after the third ligature, by the superior profunda with the radial recurrent, and the inferior profunda with the posterior ulnar recurrent (the anastomotic being now cut off). 3. It is not easy to explain the arrest of the hæmorrhage by the second ligature, which did not embrace the artery; but it is probable that a very slight movement of the arm (unstable as it is after excision) may have caused the end of one bone to compress the vessel from which the bleeding was taking place.

The other post-mortem appearances of interest consisted in distinct pyæmic abscesses in the lungs, liver, and one kidney, with localised empyema on the right side as the result of the bursting of one of the abscesses.

LONDON HOSPITAL.

NOTES OF CASES OF DISEASE OF THE NERVOUS SYSTEM.

(Under the care of Dr. HUGHLINGS JACKSON.)

Migraine, Chorea, and Rheumatism.—Dr. Hughlings Jackson has been struck by the intimate relation there seems to be between chorea, migraine, and rheumatism — a relation which he believes was pointed out by the late Dr. Anstie. It is seen in several ways. Patients who have chorea are found to be subject to severe paroxysmal headache, not often, however, preceded by ocular spectra. In several recent cases of unusually severe migraine, Dr. Hughlings Jackson has found that the families of the sufferers have been subject to rheumatic fever. In patients recently admitted into the London Hospital for rheumatic fever a fair proportion have been subject to headache, but the facts gathered from the few patients as yet interrogated are vague and inconclusive.

During a period of rather more than a year Mr. G. E. Herman worked with Dr. Hughlings Jackson on the clinical history of chorea. Notes of seventy-six cases were taken. As regards headache, it appears that fifty-three of the patients suffered from paroxysmal headaches. In four information about headache could not be, or was not, obtained. Out of the fifty-three headaches, thirty-one were constantly attended with nausea or vomiting. In fourteen there were ocular phenomena—temporary amblyopia or spectra. In eleven there was giddiness.

On Recovery from Double Optic Neuritis; no Amaurosis.—It is well known, or ought to be, that optic neuritis may exist in a patient who can read the smallest type. There are two patients in the hospital now who have severe neuritis, great swelling with effusions of blood, whose sight, so far as they know, and so far as reading goes, is quite good. Such cases are very common in physicians' practice, and Dr. Hughlings Jackson never tires of insisting on the great clinical importance of the facts they show. It is not even an exaggeration to say that neuritis is in physicians' practice far commoner with good or only slightly impaired sight than is absolute amaurosis from any cause.

It is to be observed, also, that optic neuritis may *pass away leaving sight good.* The following is a case of recovery from optic neuritis. It is not a case of recovery from amaurosis, for there was no defect of sight at any time, except, of course, the confusion of vision due to the palsies of the sixth nerve. A man twenty-eight years of age attended as an out-patient Dec. 4th, 1871, for complete deafness of the left ear, slight deafness of the right ear, almost complete palsy of the left sixth nerve, paresis of the right sixth, very trifling weakness of the superficial muscles of the left side of the face, and irregularly distributed numbness of both sides of the face. There was no paralysis of the limbs. These symptoms were probably owing to intracranial syphilis; they rapidly passed off under the use of iodide of potassium in large doses. For this reason the case is one of practical interest. Such a *medley* of symptoms is very significant of intracranial syphilis. But there is one matter of still greater importance. The patient had acute and severe double optic neuritis, and yet had no defect of sight. The neuritis was passing off when the patient ceased to attend, but being written to he presented himself in October, 1872. He was quite well. He could then, as before, read No. 1½ Snellen easily. To indirect examination no abnormality was discoverable in his discs; to direct examination the changes were trifling, only such as are frequently seen in patients who have no cerebral symptoms.

It may be objected that in this case the neuritis itself was syphilitic; but it differed in no obvious way from neuritis the consequence of glioma. Dr. Hughlings Jackson always gives large doses of iodide of potassium in cases of acute and recent optic neuritis; but for the very reason that he *always* gives this drug he is unable to declare whether the recovery is really due to medicament. His impression is that it is due to the drug, and therefore he does not feel justified in omitting it in any case. He believes there would be less blindness than there is if neuritis were discovered earlier and treated vigorously.

NEWCASTLE-ON-TYNE INFIRMARY.

NOTES ON A CASE OF CANCER OF THE STOMACH.

(Under the care of Dr. Byrom Bramwell.)

John H——, aged twenty-nine, was admitted on the 29th October, 1874, complaining of difficulty in swallowing, shortness of breath on exertion, emaciation, and debility. The patient stated that for some years he served in the army, that lately he had been working as a miner (after his death it was ascertained from his friends that he had been for some time engaged as a prize-fighter, and that he had on one occasion received a severe blow beneath the belt). Until his present illness commenced he enjoyed excellent health. Thirteen weeks ago he got cold while working in a damp pit, shivered, became feverish, and began to cough. These symptoms were soon followed by a pain in the abdomen and a catch in the breath. At the end of a week he experienced some difficulty in swallowing. He had been gradually getting worse and had rapidly lost flesh.

On admission he was sallow and emaciated; the left pupil was slightly larger than the right. He complained of pain and tenderness on pressure in the epigastric region. No tumour could be felt. It was difficult to make a satisfactory examination, as the abdominal walls were very hard and tense. On inspection the abdomen looked natural. On percussion there was dulness in the epigastric and left hypochondriac regions. Patient complained of difficulty in swallowing; the food, he said, seemed to stick at a point corresponding to the lower end of the sternum. The obstruction was not constant; sometimes he swallowed a piece of meat quite well, at other times water choked him. When the bolus of food or mouthful of water did go down it caused him to take a sudden gasp. After eating he felt a weight and fulness in the epigastrium. He never vomited. The appetite was good, tongue clean, bowels regular. A faint systolic murmur was heard in the pit of the epigastrium, intensified on pressure. Liver dulness measured 3½ inches. He complained of cough and shortness of breath. No physical signs of disease in the circulatory or respiratory organs. Radial pulse 80; respirations 20; temperature normal; urine, sp. gr. 1010, acid, light-coloured, slight mucous deposit, containing a little pus, trace of albumen. He was ordered a tonic mixture, and the ordinary diet of the house.

Nov. 3rd.—Difficulty in swallowing gone. He thinks he is a little better.

8th.—Swallowing worse than ever. Feels uneasy after eating; is much troubled with wind. To have a mixture containing bismuth, aromatic spirits of ammonia, spirits of cinnamon, and infusion of calumba. Urine normal.

16th.—Shortness of breath on exertion worse. The respiratory murmur is faintly heard over the left base, and there is here some dulness on percussion. A few sibilant râles are heard over the rest of the chest.

18th.—Complains of great pain and tenderness in the left hypochondrium and in the epigastric region. The abdomen is distended, tympanitic on percussion, except over the painful part. The bowels have been freely opened. To have two grains of opium three times a day until the pain is relieved.

19th.—No better. Complains to-day of tenderness on pressure in the left lumbar region. Urine: sp. gr. 1030, no albumen, a trace of sugar, a few pus-cells and oxalates.

23rd.—Feels and looks worse; the slightest pressure over the upper part of the abdomen causes intense pain.

27th.—At 10 P.M. last night was attacked with severe pain in the upper part of the abdomen; the pain was relieved by a large opiate. Bowels have been three times opened; he passed some lumps of matter which looked like fat. Hepatic dulness now measures five inches. Is very thirsty; tongue dry and furred; the dulness over the base of the left lung is more marked; vocal resonance and the respiratory murmur are very faintly heard over the dull area.

Dec. 3rd.—No better. The feet and ankles are slightly swollen. Urine contains a decided trace of sugar; no albumen.

6th.—Severely purged; the matter passed was liquid, of a dark colour and very offensive smell.

11th.—Vomited a quantity of very offensive-smelling dark liquid, which under the microscope was seen to consist of blood, pus, and much granular and molecular débris.

12th.—The vomiting and purging still continue, in spite of all treatment. The matters passed are of the same dark colour and offensive odour. The patient died at 8 P.M.

Autopsy, forty-two hours after death.—The body was much emaciated. The peritoneal cavity contained a considerable quantity of offensive pus; the peritoneum was coated with recent lymph; the intestines were bound together by recent adhesions. The stomach was firmly attached by its sides and posterior wall to adjacent structures. On opening the organ, a ragged, black, fungoid-looking mass, the size of a child's head, was seen projecting into and almost filling the cavity; the fungoid growth sprang from the posterior surface of the organ; the base or attached margin was hard and indurated, fully the size of the palm of the hand; the coats of the organ were thickened for a considerable distance round the tumour. At the point where the organ was adherent to the liver the coats were very much thinned, and it was here apparently that the peritonitis had commenced. The œsophageal opening was situated beneath the tumour, in direct contact on its right side with the indurated mass forming the base of the tumour. There was no narrowing of the orifice, but the projecting fungoid mass completely overlapped the opening, and closed it in a valvular manner; in contact with the posterior surface of the organ was a mass of enlarged glands; a chain of enlarged glands surrounded the aorta. The pancreas was enlarged and indurated; the spleen was large; the liver was pale and fatty; the other organs were healthy.

On microscopical examination the fungoid mass was found to be composed of fibrous tissue, bloodvessels, and cells of various forms—round, oval, pear-shaped, cylindrical—containing generally a single large nucleus and one or more nucleoli. The cells were for the most part rather less than the cells of healthy hepatic tissue. The bloodvessels and fibrous tissue formed villous-like projections; the surface of these projections was thickly covered by the cells. The same form of cells was found in great abundance in the enlarged glands in the pancreas.

Remarks.—The interesting features of this case are:—1. The age of the patient, twenty-nine. It is exceedingly rare to meet with cancer of the stomach in persons under thirty years of age. 2. The great extent of the disease in the stomach itself, and in surrounding structures. 3. The almost total absence of stomach symptoms—vomiting, &c. 4. The peculiar manner in which the projecting mass of tumour blocked up the œsophageal orifice, explaining the dysphagia and preventing vomiting. 5. The nature of the tumour. It had apparently been a solid cancer, which had undergone extensive softening and ulceration at its free margin, and was not a true villous growth. 6. The extensive peritonitis. 7. The close relation which the temperature bore to the pulse, the slightest variation in the one being accompanied by a corresponding variation in the other, as seen in the following table:—

Table of Temperature and Pulse.

Date.	Time of Day.	Temperature.	Pulse.

Reviews and Notices of Books.

Clinical Lectures and Essays. By Sir JAMES PAGET, Bart., F.R.S., D.C.L. Oxon., LL.D. Cantab., &c. Edited by HOWARD MARSH, F.R.C.S., Assistant-Surgeon to St. Bartholomew's Hospital and to the Hospital for Sick Children. London: Longmans, Green, and Co. 1875.

IT is too true that medical and surgical works of the practical but philosophical type are becoming with us more and more rare every year. With a few happy and notable exceptions, the crude theories and ignorant speculations of untrained observers and unskilful writers seem to have permanently taken the place of the learned but practical writings of the Coopers and the Bells, of Lawrence and Brodie, and of many others eminent in the various departments of surgery; and of Sydenham and Graves, of Bright and Addison, and others famous in the annals of English medicine. Book-writing has latterly almost degenerated into a mere trade; and to such a degree has the evil practice grown that a book (the smaller and the more ambiguous the better) has become in the eyes of the public almost as essential as the credentials of a legal qualification to practice and the brass-plate on the door. Persons worldly-wise do not scruple to advise a young man to write a book on something—it matters little on what—to catch the public and the professional eyes; nay, they even insist that, under the present conditions of competitive life, it is impossible to gain anything like rapid success without doing so. Hence the press literally teems with medical works, many of which are not worth the ink with which they are printed. But these effusions, doubtless, answer the great purpose for which they are really intended—namely, to act as a respectable mode of advertising and to entrap the credulous. The practice is not, therefore, likely to grow less spontaneously.

How different is the work now before us. Written by one who for long has been the acknowledged chief of English pathologists, and distinguished as a careful, well-educated, and painstaking surgeon, who has enjoyed one of the largest experiences of modern times, this book is of real worth. It is, indeed, difficult to decide whether to admire most the modesty and the simplicity of the author, the quiet and unassuming tone of the lectures, or the truth and accuracy of the clinical records, illustrated and illuminated as they are by a scientific and philosophical observation. Such a work by such a man is altogether beyond the pale of criticism. It is an authority we must at all times respect, even though we may not in every instance acquiesce in its judgments. We shall therefore briefly review some of the chief points of the book, which, it must be understood, consists for the most part of lectures that have already appeared in our columns or in those of other medical journals, and in the St. Bartholomew's Hospital Reports. Many of them are, doubtless, already well known to our readers. To these lectures, therefore, we need not refer beyond urging those who have not already read them to obtain them at once and study them carefully—for, clear and concise as they are, they require to be read carefully if we would enjoy them to the full,—and recommending those who have already read them to read them again.

The articles on "Nervous Mimicry," and on "Dissection Wounds," which appeared some time ago in our columns, will prove entertaining, even though every word be known by heart. At present, however, we would call attention more particularly to the article on "The Calamities of Surgery," and the suggestive "Notes for the Study of some Constitutional Diseases." In the former article Sir James Paget deeply but delicately probes the "surgical conscience," and points out many of the sins of commission and of omission into which surgeons, himself amongst the number, have fallen, and into which we are all liable to fall unless the greatest care be exercised. Of how small a matter may militate against the success of an operation, aye, even cause the death of a patient, Sir James furnishes several illustrations from his own practice, and from that of others. Every function of the body must be examined, all the details of the operation and of the dressings must be carefully and unremittingly attended to, and the closest attention must be paid to the personal hygiene of the patient. There is one subject on which Sir James touches which has more importance than is usually attached to it. It is that the surgeon should not operate in his own house. How many patients have died from the chill caught on their way home, and in how many instances has life been jeopardised by carelessness on the part of the patient after leaving the surgeon's house. More than this, we may add that there are prudential reasons personal to the surgeon that should deter him from operating in his own house. The patient may die from chloroform, or from fright, or from some other cause. Such a catastrophe has occurred more than once within the last few years.

The "Notes for the Study of some Constitutional Diseases" would be spoiled by being summarised. They must be read in their entirety to be properly understood and fully appreciated. Accepting the evolution theory, Sir James argues in favour of the modifications of diseases in hereditary transmission. He states, for instance, "that in members of cancerous families, not only recurrent tumours and rodent ulcers are much more frequent than in other families, but fatty tumours and harmless warts and nodular growths of skin may be explained on a theory of evolution of disease." With his usual caution he then "hazards a guess," "that the evolution of cancer in many generations may be studied in the whole group of hereditary diseases." Beginning in monstrosities by excess, differentiations from the normal type may show themselves in the form of simple overgrowths, or as innocent tumours, "thence to recurrent tumours composed of the same structures in embryonic forms, till genuine cancer is arrived at." But if there be *evolution* of cancer there may also be a process of *involution*, and some cases of recurrent and simple tumours met with in families in which cancer occurs, may perhaps be gradual reversions to the healthy type of shape and structure. Processes of evolution and of involution are probably always going on, so that those manifestations of cancer, gout, or tuberculosis which appear to be primary, may in reality be inherited. In fact, Sir James does not believe that any of these conditions can arise from any external conditions whatever, and independent of inheritance. We must confess that to our mind this statement requires considerable qualification. Passing by the considerations of evidence of inheritance, mutations of local and constitutional diseases, and the lesser signs of constitutional diseases, we come to an entertaining and instructive section on the discovery of constitutions by injury and disease. We should like to dwell on the thoughtful remarks concerning time in constitutional diseases, successions of constitutional diseases, and the coexistence and combinations of constitutional diseases, if it were not that they will not bear being summarised, but must be closely studied, and cannot be repeated except in the author's words.

The part performed by Mr. Marsh has been well done. The notes appended to the work are written by this gentleman, and enhance the value of the text if they cannot exactly be said, in the words of Sir James, to "amend the chief of my defects."

We need scarcely say that we heartily commend this excellent work to our readers.

The Pathological Anatomy of the Nerve-Centres. By E. LONG FOX, M.D., F.R.C.P. London: Smith, Elder, and Co.

THE labour which has been expended on pathological anatomy during the last twenty years has increased much our acquaintance with the minute processes which underlie disease, but in no department has it resulted in such substantial additions to our knowledge as in that of the nervous system. The microscopic research in other branches has added many new facts to those which were known before, but has left the chief landmarks of the science very much where they were. In the nervous system it has been different. Improved methods of microscopic investigation have added new regions to the field of study. We now know the pathological anatomy of many diseases of which twenty years ago nothing was known. Locomotor ataxy, the various forms of sclerosis, and we may add progressive muscular atrophy and infantile paralysis, are instances of sufficient point.

The field is a very wide one, and a conspectus by a competent hand of what has been done in it is a contribution to the busy worker not to be lightly valued. We welcome a work such as that which Dr. Fox has given us, which fulfils this object to some extent. It consists of lectures given either as part of the course on pathological anatomy at the Bristol Medical School, or as clinical lectures, and it is intended to bring together, the preface tells us, "in a convenient and readable form for the use of students and practitioners, much that is now scattered in publications of many kinds, as well as some of the pathological experience that has come in the author's way in the course of seventeen years of hospital work." The first part contains lectures on general pathological processes, while the second part gives an account of the mode in which these pathological results are grouped in certain conditions which symptomatically have received special names, and in it are included chapters on various individual diseases of the nervous system. The author has evidently studied carefully by practical observation and wide reading, and his account of each disease gives what is on the whole a fair account of the present state of our knowledge on the subject. The account, indeed, is in many instances almost too "fair," and little attempt is made to digest the detailed statistics and quotations which make up no small part of the work. The book, however, is readable enough, and will be very useful to those for whom it is immediately intended, but to the special student of the pathological anatomy of the nerve-centres it is somewhat disappointing. As a result of its origin, and contrary to what its title suggests, it is made up as much of clinical as of pathological description. The style of the book is in some places careful, but in others it hardly possesses that precision which is desirable in a scientific treatise, and frequently bears marks of hasty writing. We doubt whether the author would, on deliberate reflection, adhere to the general statement that "successive attacks of paralysis, quickly recovered from, afford almost certain proof of the existence in the brain of miliary aneurisms"; and it is hardly admissible, with our present terminology, to state that "convulsions depending upon epilepsy may be produced by tumours growing from the bone."

The first lecture is devoted to the various congenital abnormalities of the nervous system, and in the second abnormalities of the vascular system are described—cerebral aneurisms, embolisms, hæmorrhage, and congestion. Inflammations of brain and cord constitute the subject of the third lecture, including meningitis, simple and tubercular, and encephalitis. The account of these conditions is, on the whole, a good one, but the morbid appearances in simple spinal meningitis are undescribed, and so also are the various changes in the membranes which are consecutive to spinal caries, and which have of late been carefully investigated in Paris. Encephalitis is treated vaguely, and sufficient distinction is not made between the cases of true encephalitis and the numerous cases of supposed encephalitis which are really due to vascular disease.

Much of the information for which such a treatise as this will be especially consulted is that which relates to the various forms of degeneration of the nerve-centres, which underlie so many diseases, and constitute the subject of the fourth lecture. The essential differences which exist between the different degenerations of the spinal cord and brain are still, to a very large extent, undetermined. The author describes in separate sections "grey degeneration" and "sclerosis," but fails to find any essential distinction between them, and considers that both must be regarded as inflammatory in nature. Their microscopic characters are the same. In each there is disappearance of the white substance of the nerve-fibres, and sooner or later of the axis-cylinders, and with the destruction of the white substance the white tint of the cord disappears also. In each the connective tissue, which normally occupies so small a space between the nerve-fibres, increases, so as to come to occupy nearly the whole area of the diseased portion. The author does not corroborate the distinction between the two forms which has been based upon the minute microscopic differences of texture, number of nuclei, amount of fibrillation of tissue, &c., and apparently agrees with those who hold that in each form the connective-tissue change is the primary one, the destruction of the nerve-fibres being the result of their compression by the newly-formed connective tissue. It is probable that the real distinction between the different forms will have to be sought in other than histological characters. One remarkable feature is the distribution of some changes according to functional continuity rather than local contiguity—a difference which suggests an essential difference in the two processes of more fundamental importance than minute variations in structure.

The two succeeding lectures are devoted respectively to tumours of the brain and to delirium. It is apparently a consequence of the origin of the book in independent lectures that these two subjects obtain an equal space and the pathological anatomy of tumours of the brain receives somewhat scanty treatment. Glioma, a tumour almost confined to the nerve-centres, and of great pathological interest, is dismissed in a few lines of most imperfect description. Delirium, on the other hand, is treated with fulness, and the little that is known and the much that has been imagined of its pathological anatomy and of its pathology are fairly described. All forms of delirium are referred to changes in the vessels or blood as their cause, the idea of primary alteration in the nerve-centres being excluded. In the succeeding lecture, on Insanity, which contains a large number of statistics and facts gathered from various sources, a similar explanation is given for the various forms of mental derangement.

The chapters on Aphasia, Glosso-laryngeal Paralysis, Facial Paralysis, Locomotor Ataxy, and other special diseases, contain a good *résumé* of the results of modern research, but no original matter beyond a few illustrative cases. The author inclines to a limited belief in the embolic theory of chorea, but holds that it cannot explain all the phenomena of the disease, and especially its relation to an emotional cause. He thinks that some other condition must be invoked to explain its occurrence, and believes that such a condition will be found in vaso-motor spasm.

The few and insignificant changes which have been found in the nerve-centres in tetanus are quite inadequate to afford an explanation of that remarkable and terrible disease. The resemblance between the tetanic state and that produced by strychnine suggests the probability that the former, like the latter, is due to a blood state. Dr. Fox hints that the defective absorption of oxygen which has been found to be a character of the blood in strychnine-poisoning may exist also in tetanus, and the result may be that vaso-motor spasm easily occurs and produces the tonic spasms. A similar defective oxygenation of the blood is the author's explanation of many of the phenomena of the epileptic paroxysm. He doubts, however, whether it is simply the effect of defective respiratory movement in the earlier stages of the fit, and thinks it rather a primary blood state in which the malady really consists, and to this he does not appear to regard the phenomena of heredity as offering any substantial difficulty.

The work terminates with an account of the lesions that have been found in the spinal cord in some cases of small-pox and diabetes, and with an outline of the results obtained by ophthalmoscopy in diseases of the nervous system.

From Vineyard to Decanter. A Book about Sherry. By Don PEDRO VERDAD. London: Stanford. 1875.

THIS little book is what it professes to be—an account of the process through which the grape-juice passes on its way from the vineyard to the decanter. After pointing out the absurdity of a gentleman who wishes to augment a moderate income by entering the wine trade, thinking he can be a good judge of that which it requires years of experience besides a natural aptitude and delicacy of taste to appreciate properly, the author observes that during the first year or two extraordinary changes that have not hitherto been accounted for occur in wines, even when made from grapes of the same vineyard, and in all apparent respects treated alike. Hence they are divided into the fino, oloroso, and basto. These are then used for making the soleras or butts forming the foundation of any given class of wine, the finer kinds resembling a liqueur. The soleras are *natural* wines. The contents of the soleras are blended to form the ordinary pale, golden, or brown sherries, and Don Pedro gives the proportion of each commonly used. He strongly recommends the use of the natural wines, observing only that it should be drunk in coloured glasses, since it is not and cannot be always bright. A sensibly written little book.

Pocket Temperature Charts proposed for the Practitioner's "Visiting List." Suggested by Dr. FOSTER, Physician to the General Hospital, Birmingham. Salt and Son, Bull-street, Birmingham.

THIS book consists of a number of leaves bound up together, and punctured with a lineal series of holes at the attached margin to admit of their being detached separately. Each leaf has on one side the name, age, and disease of the patient, with columns for recording the morning and evening temperature, the pulse and respiration, and the amount and specific gravity of the urine; and on the opposite side are spaces for a brief record of the signs and symptoms, daily progress, and treatment of the case. Altogether it strikes us as an excellent suggestion, very ingeniously worked out, and very suitable for practitioners and others for whom it is intended.

THE
GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

Session 1875.

FRIDAY, JUNE 25TH.

THE letters of Miss Jex Blake and Mr. Arthur Norton on the medical education of women were ordered to be acknowledged, with a statement that they had been considered by the Council.

With reference to a letter from Mr. Shuttleworth respecting the registration of foreign degrees, the following resolution, which was moved by Dr. Sharpey and seconded by Dr. Rolleston, was unanimously adopted: "That it is desirable that the Council should take into consideration, at a future meeting, whether, with a view of furthering the desire of extended accomplishment in medicine and science among the members of the medical profession, it may be advantageous to make it lawful for the Council to insert in the Medical Register, after the name of a person registered on qualifications in medicine and surgery obtained in the United Kingdom, the appropriate title indicative of a medical degree obtained, after study and examination, in a foreign or colonial university approved for this purpose by Her Majesty's Privy Council on the recommendation of the Medical Council."

It was then resolved that Mr. Shuttleworth's letter should be acknowledged, and that he be informed that the Council had reserved the consideration of the subject to which it related.

A report was read from the committee appointed to consider the proposed repeal of parts of the Medical Acts, submitted for the consideration of the Council by Mr. Rickards, the Speaker's counsel. It stated that, in the opinion of the committee, the repeals proposed were merely formal, and that the whole of Clause 46, especially referred to by Mr. Rickards, might be safely repealed.

Some objections were raised to the repeal of Clause 46, on the grounds stated at a previous sitting of the Council; and, on a motion for the adoption of the committee's report, an amendment was proposed and carried that it be adopted, with the exception of that part relating to the repeal of the clause in question.

The following members of Council were appointed on the Business Committee:—Dr. Bennett, Dr. Humphry, Dr. Andrew Wood, Dr. Aquilla Smith, Dr. Sharpey, and Dr. Quain.

Dr. PARKES then moved,—That, in reference to the communication from the University of Oxford relative to qualifications in State Medicine, the Council considers that, in the interests both of the public and of the advancement of medical science, the principle embodied in the Conjoint Examination Scheme for licences to practise medicine and surgery should be extended to any licences or certificates in State Medicine or public health."

Mr. QUAIN seconded the motion, which, after a short discussion, was agreed to.

ADMISSION OF WOMEN.

The Council then resolved itself into committee for the consideration of the amended report of the committee on Mr. Simon's letter.

Mr. TURNER moved the adoption of paragraph A, which was as follows:—"In reply to the communication addressed to them by the Lord President of the Privy Council, the Medical Council have to state that they have felt bound to consider the whole question of the admission of women to the medical profession."

The motion was seconded by Dr. QUAIN.

Dr. BENNETT.—I have an amendment to offer to this motion,—"That, instead of Paragraph A as now read to us, the following be adopted: 'Sir,—In accordance with the request of the Lord President, as conveyed in your letter of the 8th inst., I have the honour to inform you that I have brought under the consideration of the General Medical Council the Bill, which has been introduced into the House of Commons by Mr. Cowper-Temple, to amend the Medical Act, 1858, so far as relates to the registration of women who have taken the degree of Doctor of Medicine in a foreign university.'"

Mr. MACNAMARA seconded the amendment.

Dr. ROLLESTON suggested that the amendment would require an entire rearrangement of the paragraphs of the report; and some time was occupied in discussing the course that should be adopted in regard to it. Dr. BENNETT contended that something more than a matter of form and arrangement was involved, but his amendment was negatived, and the paragraph of the committee's report was adopted.

Mr. TURNER.—The next paragraph in the report is marked B. I will move its adoption. "The Medical Council are of opinion that the study and practice of medicine and surgery, instead of affording a field for exertion well fitted for women, do, on the contrary, present special difficulties which cannot be safely disregarded."

Sir WM. GULL seconded the motion.

Dr. PARKES.—I beg leave to move an amendment. I propose to leave out the words "which cannot be safely disregarded," and insert the following, "But the Council are not prepared to say that women ought to be excluded from the profession."

Dr. PYLE seconded the amendment.

Sir WM. GULL.—I see no objection to the admission of those words, and so far as I see I should vote for the amendment.

Mr. TURNER.—I cannot accept those words.

Mr. QUAIN.—I may state that words of that kind were used originally, and that it was to conciliate support that they were afterwards altered as they now stand.

Mr. TURNER.—Will you allow me to state that there is no statement in the report that women ought to be excluded from the profession? The amendment moved by Dr. Parkes does not, to my mind, add anything to the strength of the position that he takes up. There is no one statement in the report that women ought to be excluded.

Dr. PARKES.—The sentence as it stands seems to imply that. It says "special difficulties which cannot be safely disregarded." That may be taken as practically an exclusion.

Dr. SHARPEY.—I feel bound to vote for the amendment. It exactly expresses my own views on the subject. I should not recommend women to enter the medical profession. I should dissuade them from entering it, but I am not prepared to say that they ought not to do so. Persuasion is one thing, denial is another; and I am not prepared to stand in the way of women entering on a career on which they think they can safely and properly enter.

Dr. ANDREW WOOD.—I think we have now come fairly face to face with the question, and I rise to give this amendment my opposition. If the amendment is carried and put as a substantive motion, or if it is thrown out, I shall be prepared myself to propose an amendment carrying out my own views; but in the mean time I think I am in order in speaking on the question of whether women should be admitted to the medical profession or not. We have been asked to enter upon that question in its entirety. Now, from the beginning of this agitation with regard to women I have always taken up one and a consistent course, but it is an honest course. I have always held that women are not adapted to the medical profession and the medical profession is not adapted to women; and I have had to stand pretty considerable volleys of abuse from that faction which carries on the agitation for the advancement of women's rights because I have sturdily stated my opinion on the subject. I have given them and their supporters all the credit of honesty and good motives; and I do think it is a hard thing that they will not, in return, give us the same credit. If we were to judge by the noise and the dust which has been kicked up in regard to it, we might imagine that the whole country, or the large majority, was in favour of the admission of women to the profession. I am not prepared to admit that. I believe that if the population, and especially if the women, of the country were polled, it would be found that there is an immense majority against it. I believe that it is a mere section, but it is a persistent section, a noisy section, a section that makes itself heard in the public press, at meetings, on platforms, and in every way that it can, in order to induce us to force—for it is a forced agitation—to force women into a position which I honestly maintain they ought never to be placed in. Many of those who advocate the admission of women into the medical profession do not know anything about either the profession or what the practice of it involves. I do believe that many of them think that you have nothing to do but to sit at home, and take your guineas to write a prescription, and there is an end of it. They do not know what toils and dangers, what perplexities and constant anxieties there are in the profession; they do not know all the repulsiveness of the dissecting-room; they do not know the bloody scenes of the operating room; they do not know a great many of those things which are even so repulsive to men that they refrain from entering the profession. The fact is, it is not adapted to all men. In fact, it is a very peculiar race of men that can be induced to study medicine, or to enter upon the practice of it, on account of the many difficulties and unpleasantnesses which beset it. I do not know whether it is the case here or not, but in Edinburgh we have ventured in our ignorance to talk of women having a particular sphere, which I have always thought was an axiom. But when we venture to talk about that we are sneered at. "Woman's sphere!" they say; "why, woman has no sphere which is less than that of man." I say that this is utter nonsense. God never meant woman for the sphere of man, and he never meant man for the sphere of woman. If a woman is pushed into a man's occupation she is as much out of place as a man when he is pushed into the occupation of a woman. Woman has a very important sphere—the sphere of her own home. She has the bearing and suckling of children; she has the training up of the young, and she has a great many feminine occupations with which she ought to be as largely employed as possible. "But," say they, "she is now at this time of day to begin to enter upon a profession which she never entered into before." Why does she go to the medical profession? The medical profession, of all others, is the one that opposes most difficulties to a woman. Why does she not go to the law or to the church? Why does she not go to a great many other occupations that would be far more congenial to her? She will have no dissecting-room to go into there; she will have no blood to encounter there; she will not have to exercise brute strength, such as a woman very seldom has, and which is required in many very important operations. Fancy a woman called to reduce the dislocation of a hip-joint. Could a woman do that? And there are a great many other things that she might be called to do on an emergency that I really think it would be painful for her to attempt, both as regards herself and as regards her poor patients. It has been said, "You are a trade's union." They say, "You are like the silversmiths at Ephesus; you are afraid that your craft is in danger, and you cry, 'Great is Diana of the Ephesians!'" They tell us that our trade will be interfered with, and that these are our reasons. I say that I repudiate with scorn these insinuations. I have been a member of the medical profession for forty years, and I believe it to be an honourable, an unselfish profession, which lavishes its skill and its labours in a greater degree gratuitously than any other profession in England, and I say, therefore, to call us a trade's union and all that sort of thing is not the way to force us into adopting any scheme that may be laid before us. There are some who think that the medical profession is the very worst that women can take to, and they would rather, if possible, keep them out of it. But they say, "Although we think all that, it is inevitable, and we must bow before the inevitable; and since it must come, is not it far better to take measures to make it easy?" Is that consistent? I maintain that it is not. Then another set of people say, "Oh, do not make such a noise about it; it is a mere farce. It is only a few women who will enter into the profession; nobody will care much about it, and in the course of a few years it will die out. They will be miserable and uncomfortable in their new position. You had better say nothing about it." What! are you going to lead these women on the ice, in order that they may be drowned? Are you going to tempt them to their ruin? I maintain that I am the honestest friend of these women when I say to them, "Do not enter a profession which I know is not suited to you." I say that honestly, and I add to that, "I cannot give you any help in getting into it." How can I logically and consistently do so? I think we are experienced in Edinburgh a little as to the evil that happens from leading women into a wrong position. Some of our professors in the University of Edinburgh led these women upon the ice. I did not approve of it. I would appeal to my friend Mr. Turner whether his comfort was added to by what was done. I will appeal to the students, whether they were made happier. I will appeal to any who know about the case in Edinburgh, whether there was not constant turmoil. The woman's question was brought into everything. Such was the rioting that we were very thankful that a court of law walked in and put an end to it, and that the women took flight to London, where they found a more congenial atmosphere; and I congratulate the London members in having them if they like them. Then it is said, "If women like to enter the profession, why not let them do so?" My friend Dr. Sharpey does not think that they are very fit for the profession. He says that they will find out their mistake before they go much further. Why not tell them clearly that they had far better not enter? But then we are told over and over again by the faction, as I must call it, that women demand women doctors. I deny that women call for female doctors, and I believe that, standing here as I do to oppose the admission of female doctors into the profession, I am, in fact, the champion of nine-tenths of the women of this country. I can say for myself, that I have taken the opinions of a great many women in all classes of the community, and of all ages, and I will pledge my honour that, with one exception only, I was never told by a woman that she would employ a female doctor. The almost invariable reply to my question when I asked it has been, "We would not send for a female doctor; we cannot confide in them; we would not trust our lives in their hands so long as we can get an accomplished, skilful, and proper medical man." Women themselves are the most inveterate and sturdy antagonists of this movement; and are we to disregard the women? No. The age of chivalry has not gone yet. Let us stand up for the women, and keep them from having their sex discredited by women becoming doctors of medicine. Another argument is that women shrink from telling their ailments to men. Well, I have been for forty years a practitioner, and I have never found that women shrink from telling their ailments to me. I believe that there are some women who would not tell their ailments to any one, either male or female, and I have had frequent conversations with some of our most accomplished accoucheurs, and they have all told me that they never found any difficulty in getting from women a full detail of what was the matter with them. I have noticed that it is exactly the most delicate-minded women that have the least difficulty in making their complaints known to a medical man. Then it is said, "Well, perhaps women may not be up to all the different departments of medicine and surgery; but surely you will allow that the natural thing would be that they should practise in midwifery." Midwifery is just the department of practice for which they are least fitted. That may appear as an anomaly. But just look at it as it is. Ninety-nine out of a hundred midwifery cases could be managed by anybody. I think that it is some Irishman who said, "It is not difficult to get the child out, but to keep it in." In ninety-nine cases out of a hundred it might be managed by anybody, but then the hundredth case might occur the very first. I ask you, would you like to entrust your wife to a female midwife if there was a case of embryulcia? Would you like to see a woman with the crotchet in her hand, or with the long forceps, pulling with all her might, and with the sweat running down her face? Would you like to see a woman in charge of a case where blood was gushing out in torrents from the womb, and do you think that she would have the readiness and nerve which would save the patient from being lost? I say that these cases of midwifery are just the very cases which are least adapted for female doctors; and it is a very curious fact, and one that is undeniable, that whereas in the last century, and in the beginning of this century, very few women were delivered by any but women, in Edinburgh (I do not know what it is in England) even the very poorest woman in the poorest close would now infinitely prefer a man to attend her, and always does employ a man. That shows that confidence has been gained in the resources of men in this practice, and that many of the dangers that formerly encompassed the practice of midwifery have been got rid of by those who are best fitted to take charge of women. Well the next argument is an appeal of political economy. We are told that there is a great excess of females, and that there is a lack of employment for them, and that you should open up to them every field of exertion that you can. Well, I agree with it; but then you must see that you open up that which they are adapted for. There are very many things that they are far better adapted for—the teaching of young children and of grown-up girls, for example. Then we find them in the public offices, such as the post-office, and other offices where, as clerks, they can sit quietly at their desks, and not be called to encounter any of those dreadful things that they must encounter if they become doctors. They are also employed in the telegraph office. Many women write for the press, and others become compositors. Others are artists, and I do not know why more should not be. Then I will just make this *argumentum ad hominem*. I would ask any member of this Council whether he would like to see his sister or daughter embracing the practice of medicine? He would revolt at such an idea; he would not like to go into the dissecting-room, as I have gone, and see five or six ladies dissecting a body, with their hands all covered with filth, and five or six male students dissecting another body two or three yards off them. They would not like to see them on their knees covered with blood. They would not like to see them liable to be called out at all hours of the day and night. We should not like to see the toiling and moiling, and noise and discomfort and disquietude to which they would be subjected. Therefore, why should we encourage the sisters and daughters of others to enter into a profession that we would not like our own daughters and sisters to take up? If there is not anything in the arguments which I have brought forward, and if the Government come to us and say, "What do you think about it?"—if they put the question directly in this form, whether women ought to be able to look to the medical profession, or to certain branches of it, as open to them equally with men as a profession and means of livelihood, say "Aye." I do not object to that; but if you in your mind believe that women ought not to be doctors, then I say, come what may, you are bound to tell the Government so. I do not think that in this question there can be any compromise. If you send any uncertain reply to the Privy Council, and if even by inference you give the Government to understand that you think that women might be employed as female doctors, you are not speaking the sentiments of your profession. I am quite sure that your opinion and your action will meet with the disapproval of nine-tenths of our profession. I say, then, in conclusion, do not let us intrench upon the softness and delicacy of the female sex. Leave them to be what God made them and what nature intended them for. I do not wish to disparage them. I love the female sex, and it is because I love them that I wish to keep them from this "mockery, delusion, and snare." Let us regard them as women who, in the language of our immortal Scotch poet, are to us in our hours of perplexity and sickness and sorrow nothing less than "ministering angels."

Dr. Humphry.—After the remarkable and admirable speech of Dr. Wood, I think it is necessary to call the attention of the Council to the fact that the question before us is not whether women are to be encouraged to enter the profession, but whether they are to be excluded from it. I confess for my own part that I have always felt regret that that question ever came before us. I have always felt that the profession of medicine was the one, of all professions, least adapted for women; but I do not feel that they ought to be absolutely excluded from it. There is no man at this table, and perhaps no man in the whole profession, who has felt more than I have done the disagreeables and the difficulties and the annoyances of the medical profession. It was with unwillingness that I entered it, and I have never got over those feelings with which I did first enter it. There is, perhaps, no one present who can feel more strongly than I do the disadvantages that women will incur who enter the profession of medicine, and far would I be from encouraging or advising any woman to enter it. Far would it be from me to encourage any daughter or sister of mine to enter the profession; indeed, it would be with much hesitation that I should encourage a son to enter it, and, in truth, I have never done so. The disagreeables which met me were so great that I would not encourage anyone else to enter. I quite admit that there are vast counterbalancing advantages. The enormous opportunities of doing good to our fellow-men in the greatest difficulties and the most trying circumstances are advantages which ought to have compensated myself long ago to a greater extent than they have, and they are advantages which fortunately have compensated others more than they have done myself. I should be unwilling to preclude any class of society, or any sex, from the opportunity of doing great good to their fellow-men. Dr. Wood has alluded to the bloody scenes of the operating-room. I have never witnessed an important operation without a woman being present there. I have often observed them, and I have often observed, too, men, not of my own profession, present, and I have often wondered why they were there. But I confess that I have thought that none of the women who were present had so strong a feeling of dislike for the thing as I had myself. Well, if women of one class are regularly admitted into our operating rooms, I do not see that there is anything in the thing itself to preclude other women from being present there. It appears to me that their line on this occasion must be determined by the consideration whether there is anything in women distinctly to render them unfit for the practice of the medical profession. If we feel that there are mental and physical disqualifications on the part of women to prevent their entering the profession, and their being useful in it, I think our bounden duty at once is to negative the amendment of Dr. Parkes; but unless we do think that they are distinctly and physically disqualified, and unless we do feel that a distinct and serious evil to the community would be incurred, I think that we have no right to declare for the exclusion of that sex. Are they, then, physically and mentally disqualified? Is there anything in our profession for which a woman is unfitted? Dr. Wood has alluded to the reduction of dislocation. Now, Dr. Wood, an eminent surgeon himself, will admit that, in the present day, reduction is not a matter of force, but pre-eminently a matter of skill. And is not the practice of our profession peculiarly a matter of skill? Well, is there anything in woman to preclude her from exercising skill as great as that of a man? If there is, then, I admit, we ought at once to forbid it. If there is not, I do not think that it is our duty to exclude her. Is there any mental disqualification? Professor Turner has alluded to the smaller size of the woman's brain; but I am sure that Professor Turner has not forgotten the fact that relatively to the size of the man there is very little difference in that respect; and I think that we all of us have sufficient knowledge of woman to feel that her mental power is very little below our own. Doubtless, in some respects it is; and I think that the examinations which have taken place at Cambridge indicate in a remarkably clear manner the difference of woman's faculty from man's. They indicate that, perhaps, in some of the more serious and harder branches of education the woman does fall a little inferior to the man, or the girl falls a little inferior to the boy; but in many other points—in facility of attention, in tenacity of memory, in readiness of application of herself, not unfrequently in accuracy and precision of statement—the girl is considerably superior to the boy. Nay, in looking over, as I have often done, the reports of the examinations, I have found it rather difficult to avoid the conclusion that the girl is mentally rather superior to the boy, and I believe in these earlier periods of life it is so; but, at any rate the boy does overtake her, and advances somewhat in front; but I do not believe that there is really any disqualification on the part of woman. Then, looking at the question morally and socially, I think it is not easy to say that the practice of medicine by women upon men is a greater moral evil than the practice of men upon women. Indeed, I am sure that it is not altogether unattended by its great moral evils. Although Dr. Wood has said that women do not desire the assistance of women, I think, nevertheless, it is certain that some do. Dr. Wood has mentioned that we tempt women to their ruin. Indeed that is not what we do, that is not the object of this resolution. Its object is simply not to preclude women from the opportunity of entering upon a certain course which she and her friends think it advisable she should take. We tempt her not. Nothing would be farther from the view of this Council than to encourage women to enter upon the profession. The point before us is, shall they be excluded? Dr. Wood has said, would we like to see women enter upon the more severe cases of midwifery? He has alluded to embryulcia. How few men there are whom we would like to trust with one's dear ones on such an occasion as that! Happily the cases are rare; and the men who are fitted for that work are very few. I am not really prepared to say that women in great emergencies are much worse than men. The woman has a remarkable readiness; I may say that personally I have often been surprised—nay, I may say put to shame, by the readiness of resource and the courage of woman, in some of the greater emergencies and some of the more serious positions of life. I have always said, "Oh, enter not that profession, and think not of it—it is one of the most unsuited to you." Nevertheless, with all that feeling, I do say that, as a matter of public justice and forming one of this board, I come to the conclusion that we ought not, as representatives of the medical profession, to say that women should be excluded from it.

Sir D. Corrigan.—This is so very important a question that I cannot permit it to pass in silence. The question before us is, as Dr. Humphry has explained it, simply that women ought not to be excluded from the medical profession. In the Senate of the Queen's University the question was discussed until an opinion was obtained from the law officers of the Crown that we had not the power of granting degrees to women, and in this discussion I was the advocate of women's admission into the profession. It may seem very inconsistent, yet it is true, that while I stated that I would be their advocate, and would oppose the application of trades-unionism to our profession and favour the admission of woman to any position which she was able to encounter, I then as distinctly stated that, supposing women obtained their medical degrees, no consideration should induce me to meet them in practice, and discuss with them the particulars of cases that must occur in hundreds every week. And if I were asked as regards the members of my own family, were they reduced to an extremity, whether I would advise either one or the other to go into the medical profession, my answer would be that I would rather see them buried. Suppose we pass the resolution in its original words, what will be the outcry throughout the country? Women will say: "You have passed such a resolution, but what are you, or who are you? You are all men, and it is your personal motives that have induced you to pass that resolution and so exclude us from a profession for which we are fitted." In my mind there is nothing that keeps up agitation so much as permitting a grievance to continue. For that reason I would remove the grievance. I would say, "You shall have the degrees if you can earn them." I do not believe that one out of 10,000 women would look for the degrees, and I know the opinion of the women themselves is in accordance with what Dr. Wood has stated—namely, that those who are most opposed to them are the women themselves. It has been stated that there are thousands of women's lives lost in Ireland from their disinclination to employ male doctors, and it is said that in the nunneries hundreds of women sink annually on that account. Now I have a very fair share of opportunity of knowing what the opinions of the women in convents are. I have asked hundreds of them whether they would like to have women doctors, and the invariable answer has been: "We would not have one of them near us." That is the opinion of the most modest women possible in any community. Supposing there was a resolution brought forward to prevent their going into other professions. Does anyone think that if the office of trombone player or big drum player in a regiment was open to women to-morrow they would offer themselves for it? Perhaps there are some who would do so, but I am sure they would soon find their level, and discover that they were unfitted for the office. I believe if we remove this grievance the agitation will subside; but as long as we twenty-four men say we will not permit women to come forward and contest for these degrees we shall be looked on as a set of jealous obstructives. With regard to the question of midwives, I think that is not before us at all at present. The question simply before us is Dr. Parkes's amendment, whether we should express an opinion that women ought to be excluded from the profession; and as to that, I say give them a fair field, they will soon find that they are out of their place, and the agitation will disappear.

Mr. Macnamara.—I think it is exceedingly to be regretted that the question of women's rights has been thrown upon this Council for solution. If we decide here in favour of admitting ladies to the medical examinations, and to the Medical Register, we are but introducing the thin end of the wedge into the solution of a most difficult problem. If women are admitted to the medical ranks, why should they not be admitted to the franchise, and if admitted to the franchise, why not to the House of Commons? I am perfectly sure that they would discharge the duties of many of the members of the House of Commons far more efficiently than some of the members of the present day, for from their training in going to balls and so on they would be able to sit up to a very advanced hour of the morning, and follow the direction of the whip as to which lobby they should go into. But much as I regret that this subject has been introduced, still I feel coerced to vote for the amendment which has been put forward by Dr. Parkes. I have heard a good deal said upon the question of the physical disabilities of women. I hear from one gentleman something about the brain, I hear from another gentleman something about the muscle. I suppose that it is meant that physically they are not strong enough to discharge the duties required of them. Well, I think that, if necessary, I could produce 20,000 women who would try conclusions with one-half of the medical profession, and the question would be decided in favour of the women (laughter).

Sir Dominic Corrigan.—What conclusions?

Mr. Macnamara.—As to the muscular strength. I dare say, Sir Dominic, I could produce in the city 10,000 or 15,000 ladies with whom you would be very sorry to try conclusions as to physical strength. It is merely begging the question to speak of physical force. There is not much physical force required to handle the stethoscope, or to handle the urinometer or thermometer, so far as medicine is concerned; and as to surgery I do not know that in that case either very much physical force is required. I would be very sorry to allow any gentleman to pass a catheter into my bladder if he was going to exert much physical force. It is not necessary in the reduction of dislocation to use much force. It is well known that that ought to be done physiologically rather than by force. If force is required, we have arrangements in all our hospitals that would enable a very delicate woman to pull the arm out of a man. As to the mental question, I think that has been thoroughly discussed. It has been said that women have not done much in the advancement of scientific problems. Well, they answer at once, "We have not had the opportunity; our studies have not been directed to that quarter." But I would like the gentleman who has made that statement to mention how many of our profession have done much for the advancement of scientific problems. I am not sure that if I were very ill I should like to be treated by a doctor who had done much for the advancement of scientific problems. I would prefer the practical physician who devoted himself to his profession. Now as to the moral side of the question. It has been said that the study would have a lowering effect on the nature of women. The most delicate-minded women that I know of are at this moment employed as nurses in hospitals. I refer to the Sisters of Charity in the City of Dublin. It would be a calumny to say that the finer feelings of these ladies have been blunted because they have attended in the most serious and critical surgical cases. There is not a more fine-minded, more tenderly-nurtured, or more admirable class of ladies than these Sisters of Charity. They are found discharging their duties well, and ably, and modestly. The Government have applied to us, and have asked us a most important question—first, whether women ought to be able to look to medical practice. We are asked now to state that there are special difficulties which cannot be safely disregarded. Of course the inference is that women ought not to look to general practice. Then we are asked as to their fitness for certain branches of it. Well, I do think that there are certain branches as to which there could not be a word of cavil, in which women might be well employed, and as to which we find great difficulty at the present moment. I think that pharmaceutically they might be well employed; they might earn an honourable income in dispensing and compounding medicines or physicians' prescriptions. It is well known that there are about ten or twelve thousand women in this division of the kingdom employed in attending women in their confinements. Well, what we would propose would be to improve their education —to make them safer in those hours of difficulty that have been so well alluded to by Dr. Wood. That is one question to which we might apply ourselves. Let them be well educated on that point. But in this report it is said the Council are of opinion that sufficient provision would be made to enable women to obtain a "legal status" as medical practitioners in this country, if an Act of Parliament were passed which should enable the Medical Council to recognise such examination or examinations as the Medical Council may from time to time deem sufficient for the purpose of granting admission of women to the Medical Register under the title of "licensed practitioners of medicine." Well, then, on one side the report goes absolutely to assist in doing it, and on the other side it goes to say that there are special difficulties to be encountered. I feel that I am bound to support Dr. Parkes's amendment, and I do think that it will relieve us of a very great difficulty indeed.

Dr. Stokes.—Sir, I wish merely to remind the Council that we are asked to advise the Government upon this matter. The question is one of extreme difficulty. There is a question raised as to the physical powers of women, and another as to the moral view of the case. Is the unsexing of women, which certainly would be threatened by a large surgical or medical education, a desirable thing? That is the question which the Government, in any future communication with us, will in all probability put. Then, to go back to the question of the physical incapability of women to perform every operation in surgery. I remember the case of a lady who was attacked with peritonitis, she before having suffered from a large abdominal tumour. She recovered from the peritonitis; and, in the course of a year after, she was seized again with the disease with great severity. She came to London, where a large ovarian tumour was diagnosed, and an operation was performed by one of the most eminent operators in such cases. That gentleman told me that, owing to the two attacks of peritonitis, strong adhesions had formed. (The disease was double; it was found that both ovaries were affected.) The adhesions were so strong that it took the entire force of the operator's body to tear them out; and so much force had to be used that after the operation he was obliged to sit down and remain in a panting condition for some time. That patient recovered, and for years was a very beautiful woman. Well, I doubt very much whether we can anticipate that women will be able to meet such an emergency as that. In obstetrics there are conditions in which the full force of the most muscular man is absolutely necessary. Then comes the moral question, Is it not very much better that a certain number of women should not make the profession of medicine and surgery a source of employment to them, or that the moral condition of the female should more or less be damaged by having to attend to matters which are in fact antagonistic to the delicacy of a woman?—is it not contrary to nature that such things should be? The feelings of women are opposed altogether to this innovation. I think in my humble way that I can confirm in every respect what Dr. Wood has said upon that point. I have made it my business ever since the agitation began, which is now several years, to inquire of every intellectual woman with whom I happened to come in contact what were her views upon the subject, and they have uniformly treated the attempt to transfer any portion of operative surgery or medicine to women as a grand mistake. Well, Sir, I do not presume to advise the Council as to the course to adopt; but I think that, as we have been consulted by the Government, it might be well that we should lay before the Government the difficulties of the subject in the first instance.

Dr. Bennett.—I think that it would ill become me to go into the broad question so eloquently opened up by my distinguished friend Dr. Wood. But I think that it is desirable that I should say why I cannot accept Dr. Parkes's amendment. My first objection is, that it is not really sufficiently cognate with what precedes in the same paragraph. The paragraph consists mainly of a statement that medicine and surgery would afford a field most unfitted for women, and then it properly ends by saying that there are special difficulties which cannot be safely disregarded. Dr. Parkes would introduce a specific statement having no absolute and necessary connexion with either of these, and would affirm that women ought not to be debarred from entering the medical profession. I object to that, therefore, as not properly coming in connexion with the paragraph. Secondly, I object to it because it goes a step further in giving our views to the Government in favour of breaking down the barrier that at present exists, and favouring the introduction of women to the medical profession. I think we should bear in mind that we have not excluded women from the practice of medicine; we have not established the corporations and universities which, by their regulations, exclude them. They are excluded as matters now stand, and the question is, whether those barriers should be thrown down, and whether we and others should give them assistance in entering on a legal status in the profession. Now, after what I have heard on this subject, and after all the attention that I have been able to give to it, I am not myself prepared to say that it is our duty, as a profession or as a council of medical men sitting here, to assist in breaking down those barriers and permitting the entrance of women upon a legal position into the medical profession. I think, quite apart from the physical and mental incapacity of women, about which much has been said, and with which I do most heartily agree, I think there are other serious objections to justify us in coming to a conclusion that their admission is undesirable in the interests of the community at large, and in the interests of women themselves. We are going considerably beyond what we are called upon to state if we specifically set before Government modes by means of which these barriers should be broken down. I think it would be sufficient for us to confine ourselves to a statement of the actual condition of things for the information of the Government, and set forth many of the conditions and objections which stand in the way.

Mr. Turner.—I should be very glad if I could see my way to accept Dr. Parkes's amendment so as not to have divided the Council upon the matter, but I really do not see my way because he cuts out certain words which I think it is important that we should put before the Lord President, and then he adds certain other words which I think are unnecessary.

Dr. Quain.—I wish to say a very few words in pointing out the gravity of the question that we are called upon to decide. We are asked to pronounce upon the admission of women to the medical profession, and we are asked because we are supposed to know the constitution and fitness of women for great mental and physical labour, and also because we know the amount of physical and mental labour required for the medical profession. We are very properly asked our opinion on these things, and we come forward to say that we believe that the medical profession is one of the most arduous to acquire a knowledge of, and one of the most difficult to follow; and if we state that a woman, by her mental constitution and physical power, is fit to enter upon this profession, the women who lead the present agitation will turn round and say, "Is there any position in social or professional life that we should be excluded from?" and that may lead to the withdrawal of a large number of women from the position in which they have been placed since creation. It is not necessary for me to state in this Council what that position is—it is the comfort of the household, the education and the bearing of children. This is a question which bears on the relation of the sexes; it is a wide and important question, and I think it would be a wiser thing for the Legislature to seek to determine it, and then if they resolve that women shall enter the medical profession, this Council can be asked how best they shall be adapted to the change.

Dr. Andrew Wood moved the adjournment of the debate.

The motion was seconded by Dr. Bennett, and carried.

It was then resolved that the Council resume for other business.

The report of the Pharmacopœia Committee was presented.

On the motion of Dr. Quain, seconded by Dr. Rolleston, the report was adopted, and the Pharmacopœia Committee was re-appointed.

The Report of the Committee on the Visitations of Examinations in 1873 and 1874 was presented.

On the motion of Dr. Parkes, seconded by Dr. Humphry, it was resolved that the report on visitations be entered on the Minutes.

The Council then adjourned.

Saturday, June 26th.

The Council met at twelve o'clock, and continued the adjourned debate on Mr. Simon's letter.

Dr. Rolleston.—I should have been glad to have voted yesterday on this question, for there was, as it seemed to me, very little to be said after the speeches of Dr. Wood and Dr. Humphry. I think that every member of the Council must have thoroughly possessed himself of the bearings of this question, for it has been before us since 1858. With regard to the speech of Dr. Andrew Wood, there was no need for him to vindicate his honesty or defend himself against public opinion. We here have no suspicions of his honesty; there is no faction here which casts any imputation on it. But if there was no need for Dr. Wood to vindicate his honesty, there is some need for me to vindicate the credit of anatomy. Why should anatomy be repulsive? Why should the dissecting-room be repulsive? It need not be so. If the thing is done properly, it need not be repulsive or loathsome. If students dissect so as to cover themselves with blood, the more is the shame for them. Dissections, like all operations in surgery, can be done badly. Even such a thing as the administration of an enema can be done in a vulgar, disgusting way, or in a way quite the reverse. If students dissect in an untidy fashion, it reacts on all their work from beginning to end. Then there is the *argumentum ad hominem* which I would apply in another way. Dr. Wood is too good a scholar not to know that the sentiment "*Homo sum, nihil humanum a me alienum puto*" applies to women as well as to men, *homo* being a word common to both men and women. Now, what are the arguments in the matter? The first great argument, against which all opposition seems to me to count for nothing, is that a large number of persons do wish for this thing. Some women wish to be doctors, others wish to have women doctors. Now, if you have a large number of the community in London, in Edinburgh, in Glasgow, in Dublin, and in the great towns of England, who desire this, I say that is in itself a reason. This feeling of people who wish to be doctors, and of people who wish to have doctors of their own sex to attend them, is a growing one, and has been growing from those savage times when woman was treated as a mere instrument of lust or a beast of burden. We have long emancipated ourselves from that stage. It is said that the very refined and delicate people are really quite content with men. My experience of women is decidedly the reverse of what many speakers have stated. I know many most refined women, the aspect of whose refinement has taken first the form of a desire to give the largest and freest scope to the energies of all, and secondly a feeling of sensitiveness, which in the course of ages has developed itself as to the two sexes being kept apart in those matters which are peculiar to women, such as midwifery. The women of greatest cultivation — women of at least as great cultivation as many of the cultivated men around this table—with whom it has been my good fortune to be brought into contact, have had just that positive feeling in favour of this enactment. As it happens I am not in relation with any female doctor—I do not know one personally; but a great number of highly refined women are strongly in favour of this great movement. I believe that of the few women who will attempt this, if you throw open the gates, many will succeed. It will not be as in many other professions, the many will attempt and few succeed, but of the few who attempt it many will succeed. There is one point which has not been touched upon at all. We in this United Kingdom of Great Britain and Ireland are responsible for the good government of a very large part of the world; and the great want of India, for example, is to have female doctors, who may bring civilisation into the zenanas and other places of that sort where men are not admitted. The demand for female doctors is greatly felt by the Indian Government. Would it not then be better that such women should be thoroughly educated, and have a trade mark put upon them, so that the Indian Government can trust them, than to have them going about without examination? I beg to state that we are responsible not only for the women who are crying out for it here in England, but for those who would be allowed to avail themselves of the well-instructed doctors of their own sex throughout that great empire of India. Then comes the question, "Are women equal to these things?" Just see what women you know of have done. Look at Queen Christina of Sweden, who used to watch Descartes' experiments, physiological and otherwise. Or look at women of our own time—Mary Somerville, Harriet Martineau, and Garrett Anderson. Those are persons who possess intelligence which I should be glad to have a small fraction of. I do not mention other distinguished women, such as our present Queen or Queen Elizabeth, but such as in our own age have been fitted for this particular work. We should not be "the first to have new things tried," but on the other hand I hope we shall not be the last "to lay the old aside." Let me close what I have to say with a sort of parable or apologue, which has often been used by people who have had, as I have now, to oppose an argument of this kind. It was used about the removal of the Jewish disabilities and the disabilities of Dissenters. A man was taken by his enemies, by a great number of honest, upright men, such as Dr. Andrew Wood. He was blindfolded, a rope was put into his hands, and then he was swung into the air and told to hang on to the rope because there was a precipice beneath him, and if he did not hold on down he would go, and there would be revolution, smash, and utter destruction of him, of public morality, and public order. So he held on for many hours, till his muscles got cramped and his ligaments were all stretched; in one word, he tasted the bitterness of death. Then they removed the bandage; he opened his eyes, and found his feet within two inches of the ground.

Dr. THOMSON.—Allow me as a teacher, as well as a member of this Council, to express my opinion in regard to this matter. It is an opinion which, as will be felt by all, I have been required to consider for a long time. I would speak first upon the wider question which we have to deal with. I think it is obvious that among the points suggested by the letter sent to us are first of all the suitability of women for the medical profession; next, whether they are more suited to one branch of the profession than another; and in the third place, the more formal question, what are the circumstances connected with examination-rules and so forth, which prevent those who wish it from accomplishing that wish. On the suitability of women to the profession, and what should be the answer referring to that point, I must say that I agree entirely with the observations which first of all fell from Dr. Sharpey. In conceding, as I do most fully, the right of women to enter the medical profession, and in saying at the same time that I do not think them altogether suited for it, I do not shut my eyes to the difficulties that present themselves in connection with it, nor even to the objections that may be made to it. I am not influenced in this by any consideration of what has been called the question of the rights of women, or by any of the moral considerations that have been put before us; but simply by a sense of justice, of what is right and proper under the circumstances. It seems to be incontrovertible that attendance on females by females is upon the whole more decent and appropriate than attendance of men upon women, and I am quite sure that I am right in following Dr. Rolleston's assertion with mine, that there are a great number of refined and delicate and cultivated women in this country who would prefer to be attended by women rather than by men. But when I say this I must recall to the attention of the Council that they have scarcely ever had hitherto the opportunity of being so in this country. The time has not come when women will be so educated that all others will be able to derive benefit from their services; but when it does come I am quite sure it will be found that the most superior women in this country, the most delicate and refined and best informed, will be most glad to avail themselves of the services of those females who enter the profession. I do not in the least share in the somewhat exaggerated fears expressed by Dr. Wood. I do not, any more than Dr. Rolleston, think that a large number of females will rush into the profession after entrance is conceded to them; and I have still less fear that those who do so will attend principally upon men. My belief is that they will devote themselves more especially to childbirth and attendance on women and children; and can any one doubt that with their knowledge of the expressions and the habits of infants and children, with all their care and gentleness, if they are properly educated they will be better attendants upon children in illness than men can be? At the same time, I think it is quite right that we should face the difficulties that undoubtedly exist, and of course it is with these that I as a teacher would have principally to contend; but I apprehend that they are not so much of a moral or general as of an administrative kind. I may say that I have no special liking for this measure; I, like others, have no desire to see any of those connected with myself entering the medical profession; but I do not see why we should deny the right to any person who may feel it to be her mission, and that she has it in her power to carry it out. With reference to teaching I may say, that such is my feeling that I would object very strongly to teaching males and females together in my subject of anatomy, so strongly indeed that I would entirely protest against it in the educational institution with which I am connected; but, on the other hand, if the Legislature should pass the measure that is suggested, and if the body to which I belong should after full consideration think right to confer their licence upon females, I should regard it as my duty to make the best of it, and to take measures to instruct those females in the manner that might be best for their advantage and for that of the public. I believe I should have no difficulty in instructing females in the whole subject that belongs to my department, provided sufficient precautions were taken, and supposing I am not called upon to instruct them along with males. If the general question is conceded, I think it is quite obvious that females may practise in any branch of the profession, but it will be very readily admitted that there is one branch which is more immediately suitable for them, as I have already said—the care of childbirth and the diseases of women and children. We have already considered what has taken place in regard to nursing in recent times. Is there anything connected with the profession that nurses do not do for men; and has impropriety arisen from that, or any difficulty? I say certainly not. With regard to the improvement of nursing we know what we owe to Miss Nightingale in the way of advancement of our knowledge and views upon the subject; and every one who has come into contact with these skilled nurses who have been trained according to her suggestions, knows what a prodigious advantage it is in a hospital, or in practice of any kind, to have to do with cultivated gentlewomen who have been properly trained to their duties as nurses. If that be true of nurses, is it not still more strongly true with regard to women who choose to enter the profession? Can any one doubt that if delicate, well-informed, well-educated, and accomplished women shall also acquire under proper regulations that skill and knowledge which is necessary for the practice of the profession, their entrance into it will not only be a great benefit in the individual instances in which they have been employed, but will be a means of introducing more delicacy into the medical profession and their relations to the public than oftens belongs to it. As to the third question of the examination rules or other conditions at present preventing women from entering the profession, I think it is scarcely necessary to offer any observation, because I dare say the Council will see the propriety of the suggestion made by the committee, that, supposing the general suitability of women to enter the profession is conceded, or measures are taken to make it possible for them to be entered upon the Register, there should be a full reservation of the rights of all universities and licensing bodies with respect to their powers to grant such licences. About the special question also which is contained in the letter, as to foreign degrees, I presume we are all at one, and there will be no difficulty there. I am still of opinion that the form presented in the report is not that in which the answer should be returned. While I consider the whole of this discussion as most useful, in fact necessary to the formation of the opinions of the Council, I do hope that the President will, according to the ordinary rules of official business, be allowed to write this answer to the letter which he has received, embodying in any way which may be proper the opinions which have been expressed.

Sir W. GULL.—I am exceedingly glad to find that the question is raised beyond the circle of corporations and universities. I think we have also raised the question, at least I hope we shall be able to raise it, out of the sex relation, which seems to me to have already occupied too much consideration. My friend Dr. Andrew Wood's admirable address had reference chiefly, I think, to the difficulties and inconveniences and doubts and disgusts which beset this question as a sex question. I do not think that is a matter for us to consider. We are not recommending to Government a conscription of women; Dr. Andrew Wood will bear that in mind; I think the whole of his argument went against the conscription of women for the medical profession. They are not to be taken *nolens volens* and made to enter it. I think if that be considered, it is entirely for the persons whom we are talking about to consider themselves whether they are fit to do it, or whether they have a mind to do it. That is a personal question that one has nothing to do with. I think, therefore, we might leave the sexual part out of consideration, except so far as our excellent friend Professor Humphry put it, for he has all the tenderness of women and yet has all the distinction of a most admirable surgeon, and I think he answers the question in his own person as far as that goes. It seems to me if we wanted an answer at all, there is an answer. But I think women must determine that for themselves. Let us consider that we are not now passing a vote, or any opinion as to whether women shall enter the profession. If so I must confess I should go dead against it, and I think I express the opinion of every man at this Board when I say that we rather think it undesirable—that if they could occupy themselves in some other way we could occupy the field equally well. Still I do not think that is a full answer, for I consider there are some parts of the medical profession that a highly trained woman could do better than a man. There are certain sex relations which might be avoided in that way with great advantage to the public. I need not say that there is a quiet scandal in certain parts of the profession about women's diseases, which probably will be got rid of by introducing high-minded, well-trained women into the practice of medicine. That is rather an important point, and the question then becomes narrowed to a very simple issue, whether we shall advise the Government that permission may be given; but I think we must give that permissive opinion with a slight *caveat*, that the entrance of women is rather dangerous. If you will look over the history of this woman's question in London, where things spring up and produce their fruits very quickly, you will see that considerable social evil has sprung up from women of a low tone of mind entering the profession. I remember there was a letter in THE LANCET about six years ago giving the social history of about 150 or 160 women who have entered the profession, and I must say I think it was anything but a creditable history. It is right to state that there are physical as well as social dangers besetting the question. I therefore do hope that we may vote for the first clause as it now stands. I do not think there is much in Dr. Parkes's addition, for it is not an amendment but an addition.

Mr. QUAIN.—The words, "That women should not be debarred from the study and practice of medicine and surgery" were in the draft of the report we agreed to; but we found that others differed so much from us that we thought it better to omit them, and though I agree with Dr. Parkes's addition, I think it would not be judicious, and I cannot vote for it. I think it is better to consult in some degree the variations of opinion in the Council, and not to include those words, for their introduction certainly created very great opposition in the committee. I myself would not advise any female member of my family to enter the medical profession, but I confess also I agree entirely with Professor Humphry in what he said about men. I would dissuade any male of my family from entering the profession by every means that I could. Yet I would not hinder a male from entering, nor would I hinder a female from entering; but when they had once made up their minds to do it, I would assist them by every means in my power.

Mr. TURNER said he felt very strongly indeed that it would not be right for him to consent to the deletion of the words relating to the special difficulties surrounding the question; while the addition of the words, "But the Council are not prepared to say that women ought to be excluded from the profession" would be interpreted by the outside public as meaning that the Council were prepared to say that women ought to be allowed to enter the profession. He therefore objected to the insertion of these additional words.

Dr. PARKES said as the clause at present stood it gave a direct negative to women entering the profession, but the object of the amendment was to state that the Council would not oppose the admission of women under proper regulations. It was of the very greatest importance that the Council should raise itself above all party and petty considerations, and judge the question on the broad principles of right and justice. If they did this the members would not do otherwise than support the amendment.

By the permission of the Council the words "which cannot be safely disregarded" were prefixed to the amendment, to read after the word "difficulties," and in this form the amendment was carried by 14 votes to 7.

On the amendment being put as a substantive motion,

Dr. ANDREW WOOD proposed that Paragraph B run thus—"One of the questions submitted to the Medical Council by Mr. Simon is, 'Whether women ought to be able to look to medical practice, or certain branches of it, as open to them equally with men, as a profession and means of livelihood?' With regard to this question of the admission of women to the medical profession, the Council, after mature deliberation, have to express their opinion that, considering the nature of the studies requisite to be gone through in order to attain the knowledge of the various branches of medicine and surgery necessary to constitute a safe and efficient practitioner; and considering that the practice of the medical profession infers, even in men, peculiar moral and physical qualities, as bodily strength, nerve, and endurance, to face much toil, anxiety, responsibility, perplexity, and danger, and that by nature women have not been so constituted as to fit them for such a profession, it is inexpedient to encourage and give facilities to women for entering the medical profession. The Medical Council, therefore, do not recommend legislation with the view of removing the difficulties in the way of women entering the medical profession." The Council, he said, was now called upon to affirm that while the profession of medicine was not fitted for women, yet they should be admitted, and that the Council was not prepared to exclude them, or, in other words, was prepared to admit them. Such would be the interpretation given to it by the women doctors. On behalf of those who like himself thought that women were unfitted for the medical profession, and that no encouragement should be given them to enter it, he desired an opportunity of having their votes recorded, and therefore he proposed his amendment.

Dr. QUAIN seconded the amendment. He considered that better and stronger reasons for not allowing women to enter the profession had never been heard than those offered by some of the members of the Council, and appearing in the Report of the Committee which Dr. Parkes had most cleverly got rescinded. When he voted in favour of Dr. Parkes's proposal it was with the hope that something much stronger would be inserted, and he believed that that was the opinion of all those who voted the same way. He should be sorry if something like Dr. Wood's amendment or the admirable letter prepared by Dr. Bennett were not substituted in the place of the paragraph which had been rescinded.

On being put to the meeting, Dr. Wood's amendment was lost, 4 voting in its favour and 12 against it.

Dr. Parkes's motion was then put and carried, the numbers being—for, 14; against, 7.

Mr. TURNER proposed the adoption of Paragraphs C and D:—"With regard to Mr. Cowper-Temple's Bill, considered by itself, and apart from its bearings on the 'general question whether women ought to be able to look to medical practice, or certain branches of it, as open to them equally with men, as a profession and means of livelihood,' the Council have found no difficulty in forming an opinion. By the Medical Act, 1858, the Council are precluded from registering foreign degrees, and consequently have been compelled repeatedly to refuse to register foreign degrees held by men. (*d*) The reason for this is obvious—viz., that the Council have no means of exercising that supervision and control over the education and examination required for foreign degrees, to which the licensing bodies of this country, whether universities or corporations are, by the Act of 1858, subjected. But this privilege, which the Medical Act refuses (and the Council believe, very properly refuses) to men, Mr. Cowper-Temple's Bill proposes to grant to women. Against such a proposal the Council feel bound to offer a protest, as being subversive of the main principle of the Medical Act."

The motion was seconded by Mr. QUAIN, and carried *nem. con.*

Mr. TURNER then proposed the adoption of the first clause of Paragraph E:—"If it should appear to the Government and the Legislature expedient that women, who desire to obtain the legal status as medical practitioners in this country, should not be debarred from obtaining that status, the Council are of opinion that it should be under some such conditions as the following."

Mr. QUAIN seconded the motion.

Dr. BENNETT moved the omission of the paragraph, as he strongly objected to laying down regulations for what might never take place.

Sir D. CORRIGAN seconded Dr. Bennett's proposal, which, after a short discussion, was negatived, and the motion for the adoption of the paragraph was carried.

Mr. TURNER moved the adoption of the following paragraph:—"That in the interests of public order, the education and examinations of female students of medicine should be conducted entirely apart from those of male students."

Mr. QUAIN seconded the motion.

An amendment, proposed by Sir D. Corrigan, to omit the words "in the interests of public order," was negatived, and the motion was adopted.

On the motion of Mr. TURNER, seconded by Mr. QUAIN, Clauses 2 and 4 as one were adopted:—"That with reference to the examination rules or other conditions which prevent women from accomplishing their wish, the Medical Council have to state that under the provisions of the Medical Act, those persons only can be placed upon the Medical Register who have been admitted to medical degrees in the universities, or who have been admitted fellows, members, or licentiates of one of the medical corporations of the United Kingdom. Should the universities and corporations be unable or unwilling to admit women to their degrees, or to admit them as licentiates or members of the respective corporations, the Council are of opinion that sufficient provision would be made to enable women to obtain a legal status as medical practitioners in this country, if an Act of Parliament were passed which should enable the Medical Council to recognize such examination or examinations as the Medical Council may from time to time deem sufficient, for the purpose of granting admission of women to the Medical Register, under the title of licensed practitioners of medicine. The education and examinations for these licences should be under the supervision of the Medical Council in the same way as is required for the other licences of this country. The Council are of opinion that any course of legislation which would interfere with the free action of the universities and corporations mentioned in Schedule A, in respect of the medical education, examination, and licensing of women, is undesirable."

The remaining paragraphs were adopted after some little discussion, with the exception of the last, which it was agreed to omit.

The Council then resumed, and adopted the report, as settled in committee. The report was ordered to be forwarded to the Lord President of the Privy Council, together with the printed minutes of the proceedings, and a copy of Dr. Bennett's proposed letter.

VISITATIONS OF EXAMINATIONS.

Dr. PARKES proposed and Dr. BEGBIE seconded the following resolution, which was adopted:—"That the Report of the Committee on the Visitations of Examinations, and on the remarks on such visitations, be considered next session, in connexion with the reports which have now been sent down for the consideration of the licensing bodies."

CONJOINT SCHEMES.

Dr. BENNETT now proposed:—"That the President be asked to inform the Council whether he is able to state in what position the joint scheme for England now is, and whether there is reason to believe that there is any foundation for the report that the Royal College of Surgeons of England have virtually seceded from the conjoint scheme agreed on by the English licensing bodies, as reported to this Council, inasmuch as it is currently reported that certain resolutions have been come to by the Council of that College respecting the appointment of examiners under the conjoint scheme in question, which resolutions are in direct contravention of certain principles of the scheme as approved by this Council."

This having been agreed to,

The PRESIDENT said: In answer to Dr. Bennett's question I must observe that no full information can be officially given, without communication with the Committee of Reference, of which Sir James Paget is Chairman, and with the bodies who have sent representatives to that committee. The scheme cannot be completed till Sir John Lubbock's Bill is law. As to the College of Surgeons having withdrawn from the scheme, that is a report as to the truth of which I have no evidence, nor have I any reason for believing it. There seems to be no ground for supposing that the College of Surgeons, which has taken much pains with a Bill that has already passed the third reading in the House of Commons, will do other than act in the same spirit as that which induced them to obtain the Bill. The College of Surgeons had, I believe, always maintained or implied their right to secure the nomination of a certain proportion of the examiners in surgery and anatomy. If this right be now insisted on, the consent of the cooperating bodies and of the Medical Council to the arrangements proposed by the College of Surgeons is obviously necessary. These circumstances show that the negotiation is one which, in its very nature, requires time, but they do not indicate that the scheme will come to an end.

On the motion of Dr. APJOHN, it was agreed "That the President be requested to ask the representative of the Royal College of Surgeons in Ireland, whether the Council of the Royal College still adheres to the scheme of the Conjoint Examiners as adopted by the King and Queen's College of Physicians, and agreed to by the other licensing bodies in Ireland, with the exception of the Queen's University, and sanctioned by the Medical Council (March 31st, 1873)."

Mr. MACNAMARA in reply said: The Council of the Royal College of Surgeons of Ireland have not withdrawn from the conjoint scheme of examination for Ireland. The Fellows, the year before last, by a large majority, decided that they could not approve of the scheme then submitted for their consideration, but did not express themselves as being hostile to the principle of a conjoint examination. The Council, nevertheless, remained pledged to the scheme approved of by this Council, but during the past year the question has fallen into abeyance. The present feeling in Ireland would seem to be that we should be very much influenced by the steps which may be taken in England and Scotland in this direction.

A letter from certain lecturers on materia medica and therapeutics in the medical schools of London, calling attention to the system adopted in the instruction in pharmacy and therapeutics, was ordered to be entered on the Minutes.

A memorial from certain practitioners in Durham was next read, calling attention to a case in which the magistrates had refused to convict an unqualified practitioner.

The memorialists were ordered to be informed that the Council had no power to interfere.

Votes of thanks were tendered to Dr. Wood, as Chairman of the Business Committee, and to the President; and the session then terminated.

THE LANCET.

LONDON: SATURDAY, JULY 10, 1875.

Whatever view may be taken generally of the correspondence which has just been published between the Lord Chancellor and the Coroner for Central Middlesex, one point will remain memorable in connexion with it, and will, perhaps, lead to most important issues. For the first time in the history of the Coroner's Court the Lord Chancellor, who holds, or rather is supposed to hold, supreme control over the coroners of England, has ventured an authoritative opinion on the duties of the coroner. In entering upon this novel course, moreover, Lord Cairns has given instructions which are altogether subversive of past rule and precedent, which will, if they be obeyed, change the whole order of the court, and establish between coroners everywhere in England and the representatives of the profession of medicine a connexion, for good or for evil, upon which will be founded a new development of coroner's law. In discussing the course which the Coroner for Central Middlesex should have taken in the case of the late Sir Charles Lyell, the Lord Chancellor says that the information-paper which was laid before the coroner by a sworn constable, and on which an inquest was demanded, was insufficient. A further preliminary inquiry, he argues, was necessary; and he adds that, in this instance, the coroner should himself have sought for such further information before proceeding to issue his warrant; that he, the coroner, as coroner, should have made a personal inquiry, or an inquiry by letter of the medical attendant (Dr. Andrew Clark) who had charge of Sir Charles Lyell up to the time of his death. It is the ruling, in short, of the Lord High Chancellor that the coroners of England possess, and ought to exercise, a discretionary power, before proceeding to their inquisition by jury, of consulting the medical attendants of persons who are reported to them by their sworn officers as having died a violent death.

It is unnecessary for us to inform medical readers of the fundamental change which, by this advice, the highest legal officer of the Crown suggests and recommends. Acted upon decisively, it will reduce the number of inquests in the most remarkable degree, and will at the same time place on the shoulders of the medical body a responsibility it has never yet had to bear, and of which it can form no adequate conception. The Chancellor, we assume, wishes the suggestion he has offered to be exceptional only in its application. But the mischief is that such a rule, once applied, can never remain exceptional. It is far too facile and convenient to remain inactive except in peculiar instances, while no possible discretion can apply to it. If the Coroner for Central Middlesex may claim the discretion, every coroner may do the same. If the medical attendant on a renowned patient like Sir Charles Lyell may be applied to, personally or by letter, by a coroner, the medical attendant of every other person, however obscure, may be equally, and with equal justice, applied to. So in the end, and in a very short time, let the precedent once be set, the coroner and the doctor will by private *tête-à-tête*, or by confidential letter, settle all inquiries preceding inquisition. The doctor will be asked first to explain, informally and privately, to the coroner the necessities or the objections to an inquest; and if the coroner thinks an inquest necessary, the said doctor will have to repeat to the coroner "on oath" and publicly that which he has stated in the privacy of the preliminary and friendly inquiry.

The question arises—How will this system, even in the most exceptional cases, work? We confess that it comes upon us with so much of the force of novelty that we can as yet wonder at it only. Up to this time we should have thought a coroner as little likely to ask a preliminary question, pending inquisition, of us medical witnesses as we should have expected the Lord Chief Justice of England to call upon us or write to us respecting a patient who was about to bring an action before him in a railway case. We should think, or at least we should have thought before the Lord Chancellor's advice was in our hands, that a coroner who wrote to us or called upon us, as suggested, was either losing his senses or was lending himself improperly to some partisan feeling or misdirection. In all our experience, indeed, we never heard of such an interference on the part of any coroner, legal or medical. The late Mr. Wakley, as is well known, was so severely impartial in respect of every medical witness that previous to such a witness being on oath in his court he would not speak to him, though he were his best friend, on the subject of the evidence; and that spirit, we believe, is as common to all coroners as it is to the judges of the higher courts of justice. With every respect to the Lord Chancellor, we think this rule works well, is the only safe rule, and is open to no discretion for its abandonment, even for an occasional purpose.

We are forced to a further conclusion. It is our duty, from a medico-legal point of view, and from a knowledge of what is best for the public safety, to insist that the recommendation of the Lord Chancellor may, in practice, prove a very dangerous one. The wisest medical men are liable to be deceived by designing and able criminals, and while designing and able criminals abound as they do it is unjust to let such an exceptional rule exist as shall give the coroner discretionary power to make, at the instance of anyone whatever, an appeal to a medical authority on the subject of an inquiry in which the same authority is a witnessing authority. Better by far that any amount of feeling should be expressed against official inquiry than that crime should be concealed under the mask of sentiment, or a pretentious exception in a mere formal instance be made admissible as a pretext for prevention of inquiry when something more than formality is demanded.

We make these observations on the Lord Chancellor's new instructions to coroners in no captious spirit. With all our admiration for his legal learning and perfect justice, we cannot fail to detect from the form and manner of his letters that the Lord Chancellor is not practically informed of the usages, precedents, and we may say necessities, of the Coroner's Court. But for that positive reason we feel assured that so just a man as he is will not maintain an error for the mere sake of upholding his authority. We trust sincerely that he will at once retract the suggestion—which, coming from him, is all but law—that a coroner, from motives of feeling, real or assumed, may take secret evidence, and allow the judgment of a witness, however eminent, to suppress the open verdict of a jury.

Before we take leave of the subject of the annual session of the General Medical Council we must try to estimate the effect and value of its proceedings as a whole. We are often asked by correspondents—What is the good of the General Medical Council, and what do we receive in return for the somewhat heavy impost which is the condition of our registration? We ourselves have not hesitated to point out with frankness the faults of the Medical Council as an administrative body, and the ways in which it fails to command the sympathy of the profession. At the same time, we have always been ready to admit the merits of the Council and the excellence of much of the work it has done. Even a hasty glance at the proceedings of the late meeting will show what a power and possibility of good resides in the Council, and that not only in a state of latency, but having its illustration in accomplished facts and in useful work. Those of our readers who are most sceptical of the good accomplished by the Medical Council will admit the force of a few facts which it is only fair to point out.

First, the Council is in more or less constant communication with the Government and with the various departments on medical questions affecting the State. In the Minutes of the late meeting will be found communications of interest, or answers to such communications, from the Lord President of the Privy Council, from the Under Secretary of State for the Home Department, from the Registrar-General, from the President of the Local Government Board, from the Counsel to the Speaker writing under direction of the Statute Law Revision Committee, from the Director-General of the Army Medical Department, &c. It is clear that the Council here is the link of communication between the State and the profession, and occupies a most important and responsible position. We must admit, too, that in *personnel* it is a highly creditable representation of all that is honourable to the profession. It would be difficult to see at one board a group of men more honourably distinguished in their several ways than is to be seen round the board of the General Medical Council. The academic culture of ACLAND; the mature scientific wisdom of SHARPEY; the younger and more impulsive, but not less scientific, justice of ROLLESTON; the dignified speech of STOKES; the quiet earnestness of BEGBIE; the emphasis of HUMPHRY; the geniality and common sense of ANDREW WOOD and Dr. FLEMING; the fine Irish mixture of the practical and the unpractical in Sir DOMINIC CORRIGAN; the knowledge of medicine and of the public of Sir WM. GULL; the knowledge of special subjects and of students possessed by teachers like Prof. ALLEN THOMSON and Prof. TURNER; the familiarity with all branches of medicine suggested by the name of PARKES, — these are qualities in the members of the Medical Council which must give its decisions more influence than attaches even to the acts of representatives of old corporations and older universities. It is true that the Council does not always make the most of its communications with the various departments. One illustration occurs to us as we write. An important letter was received in October last from the Registrar-General in reference to the Act for civil registration of births and deaths, and inviting suggestions from the Council on the new form of certificate. An answer with many admirable suggestions was made by Dr. ACLAND. But not one word was said by the President as to the great evil, we fear sanctioned by local registrars in some large districts, of receiving certificates from unqualified practitioners. Surely the opportunity was most appropriate for a word on this sore evil from the official representative of legal practitioners; but the word was not spoken. Still it is evident that a body composed as the Medical Council is must have great influence, if it likes to use it. One happy example occurs in the Minutes of the late meeting. Until lately the Consolidated Orders of the Poor-law Board have required a Poor-law medical officer before amputating to procure the advice and consent of a member of the Royal College of Surgeons of England, or some fellow or licentiate of the Royal College of Physicians of London. This order seemed to imply that there was something specially virtuous in the advice of members of two London corporations, and was clearly at variance with the spirit of equality of the Act of 1858, which put the members of all similar Colleges of the United Kingdom on the same footing, and gave them imperial privileges. This inconsistency was ably pointed out by the President of the Council to the President of the Local Government Board, and has been removed by the rescinding of the above requirement and the substitution of a new provision on the subject, placing all legally-qualified surgeons in the same category for this purpose.

Not only has the Council considerable influence with Government and the various departments, but it has still more influence on the various examining bodies of the country. This is shown by the spirit in which the various recommendations of the Council on the question of examinations and the reports of the Visitors of Examinations have been received almost universally. It would be unjust not to give the Council credit for the greater efficiency and strictness of examinations now as compared with ten or fifteen years ago, and with a design to make them still more practical and real tests. Not only so, it was suggested at the late meeting by one or more speakers, and in a report of the committee for examining the remarks of the licensing bodies on the reports of the Visitors of Examinations, that the Council should vindicate its title to be considered a Council of Medical Education by an inquiry into the modes of teaching as serious as that which it has carried out, with such good effect, into the modes of examination. This is a most important suggestion, though it yet remains to be seen whether the Council is equal to giving it due trial and effect. The rejection of large numbers of students every year indicates a tremendous failure somewhere in the work of education, and it has probably been too easily taken for granted that only students are to blame for this failure. Here we must leave the Medical Council. We do not consider it perfect, either in constitution or action; but, considering its imperfections, it has done good work, and demands the respect of the profession.

◆

The deputation which last week waited on the Home Secretary, to urge on him the importance of legislative provision for the treatment of habitual drunkards, had the support, in name or presence, of members of our profession who were fairly representative of its most influential portion. We are glad to perceive that the matter is not to be allowed to sleep. The importance of the subject is not easily exaggerated, and so much has been done in awakening public attention to its urgency, that it would be sad if the labours of its late advocate were allowed to remain without result. No more strenuous efforts have been made in the cause of social reform than those which Mr. Dalrymple devoted to the cause which he had so much at heart, and to which he gave up the best years of his life. His efforts commanded the entire sympathy of our profession, and to a large extent their approbation also. The evil which he sought to remedy presses itself on their attention with constant and peculiar force, and it is well that the initiative in the attack upon it should be taken by them.

The task which the deputation had before them was threefold. They had to point out the urgent need for fresh legislation on the subject, to show that legislative interference would have a reasonable prospect of success, and to endeavour to prove that such interference would be wise and practicable.

The first part of their duty was an easy one. The evil is only too obvious. Drunkenness confronts the social reformer as the first and mightiest obstacle in his path, productive of many other obstacles. The extent, the degree, the gravity of habitual intoxication are admitted by all. The evil can at present be dealt with only in one manner—by an attempt to obtain voluntary abstinence from intoxicating drinks on the part of those who are unable to resist the temptation to excess which habitual indulgence produces. It is here that some other mechanism is required. There are many who are unable even to attempt the path of voluntary reform; there are still more who fail in every effort to maintain a footing there which has been once secured. The problem that presents itself is this:—These cases cannot be reached by means at present available. The probability of their extinction, or material reduction in numbers, by a process of radical cure by education and refinement is very slight. If successful it can only be after many generations have passed, during the long years of which the evil is to go on, unchecked by direct interference. Either, then, it must be left alone, or some fresh means must be devised and employed to make a direct impression upon it.

Absolute forced deprivation of alcohol would appear to be the only means of lessening the tendency to its excessive habitual consumption. And then the second question comes: Are we justified in anticipating that such forced deprivation would attain its object—would enable the individual subsequently to practise with success that voluntary abstinence which he could not previously achieve? The verdict upon this point of those qualified to judge has varied, but, on the whole, it is hopeful. There can be no question that in the cases in which successful voluntary abstention has been practised, the craving for alcohol in time becomes far less intense, until it ultimately ceases altogether. Analogy forbids us to doubt that the case is the same with the more severe cases of dipsomania; that in them, too, the tendency to drink is reduced by abstinence to more manageable limits or removed entirely. The chief difficulty is the facility with which relapses occur. A single drinking bout will place the patient almost in the same position of inordinate desire and powerless will which in the first instance needed restraint, and this necessitates a repetition of that restraint. But there is reason to believe that even the cases which relapse may ultimately be successfully treated by repeated restraint. The testimony to the value of such treatment which we have from the other side of the Atlantic is most encouraging. The experiment has been tried there with a fair measure of success, a measure sufficient at any rate to warrant us in following the example set before us. It is an encouragement, too, to learn that an observer so acute and experienced as Sir Thomas Watson is now convinced of the possibility of recovery, which he once doubted. We may conclude that the probability of success is sufficient to justify the experiment.

The question which remains behind is the most difficult of the three, How can the needed restraint be applied? The need is urgent—the remedy desirable: can it be employed? The opinions of authorities on legislation have differed regarding the practicability of restraint in these cases. Our readers are aware that the proposed measures have been of two classes. One has contemplated the detention in a proper institution, during their dipsomaniacal paroxysms, of those who, in clearer intervals, have placed themselves under effective supervision. At present no means exist of detaining those who have so placed themselves. A man may go into an institution, may beg and implore the authorities to retain him there for three months, and to keep all intoxicating drinks out of his reach; his friends may join in the request. A week afterwards, when the intense craving for the stimulant which follows the first deprivation of alcohol has bewildered his reason and paralysed his will, he may refuse to stay, and in spite of his friends' request, and his own expressed desire, he cannot be detained. To provide such power of compulsory restraint, to be submitted to voluntarily, is one object of such measures as those which have from time to time been before the public. It is not easy to conceive any circumstances in which such power would lead to injustice; it would traverse no fundamental principle on which society is organised; it would involve no necessary hardship to the individual, and it is probable that it would be productive in a large number of instances of incalculable good.

But the effect of such a provision would be limited to a narrow class, and to the less severe instances of the evil it is proposed to attack. Only among the upper and middle classes, probably, would dipsomaniacs be found willing thus to give up their habit by an indirect renunciation. The worst cases are incapable even of this, and the drunkenness among the lower classes would be almost entirely beyond the reach of such a measure. Hence the proposals of the late Mr. DALRYMPLE were much more comprehensive, and included provision for the involuntary restraint, at the instigation of friends, or on the motion of proper authorities, of all those who come within the range of the term "habitual drunkard." It is evident that such a measure, involving the application of a treatment hitherto reserved for the criminal or the confessedly insane, to those who, according to the common interpretation of the terms, are neither criminal nor insane, involves a new principle in practical sociology of no small importance to all members of the community, ebriate and inebriate alike. The system is obviously open to many difficulties, theoretical and practical, to which we may return more fully on another occasion. Those difficulties, the advocates of repressive measures urge, are not insurmountable, and should serve rather to stimulate than damp the ardour of those who feel strongly the pressing evil of habitual intoxication.

◆

THE subject of Competitive Examinations is just now exciting a good deal of attention both in and out of Parliament. On the one hand, it is urged that this system secures what practically no other system does — viz., the throwing open of public appointments to all alike, so that what previously required political or social interest to procure now requires brains and culture; that by open competition you test the only qualities in the candidates capable of being tested, physical inefficiency being guarded against by medical examination; and that it is altogether the fairest system for distributing public appointments, among the middle classes especially, and, on the whole, the best method for securing efficiency. Theoretically, no doubt, it seems an excellent method; and, practically, it is extremely difficult to provide a good substitute for it. The old plan of patronage is founded on a wrong principle, and is obviously open to abuse. On the other hand, it is urged that examination does not gauge intellectual capacity and sound training; that it does not even attempt to test qualities of judgment, common sense, and character; that it encourages a process of rapid and superficial education which tends to debilitate rather than strengthen and discipline the mind; that it frequently injures the health; and that, while the system secures at best a high average in the successful competitors, it frequently excludes the best men. When the examination really tests the reasoning faculties and judgment as well as the memory the system is undoubtedly a good one as far as it goes, but it is questionable whether it is not an inadequate and inapplicable method for some kinds of appointments. Let us take the army and navy, for example. As regards the latter, we have recently had the report of the committee appointed by the Admiralty to inquire into the system of training the naval cadets. The committee expresses its entire disapproval of the present system of entry by competition. The hard preparatory study—amounting to ten hours and more daily—in the case of boys from eleven to thirteen years of age must be injurious by curtailing the amount of open-air exercise and the amount of sleep required to keep boys of this age in good health. Then, again, the mental worry and anxiety attending the preparation for an examination, the work at high pressure in the case of very young boys, especially if delicate or of nervous temperament, must, we think, prove injurious to them in more ways than one. They are not in a position to do justice to themselves in their subsequent studies whilst suffering from the effects of previous overwork; the mental tension prevents their assimilating properly what they learn, and hard study at such tender ages disgusts them with books; the overtaxed brains get exhausted, and a condition of mental nausea is induced every bit as much as their systems would become nauseated if they ate too much or were fed on too rich a diet. No wonder that many of these lads had a jaded and pallid appearance. Again, it seems monstrous that a boy's career in life should be finally decided by his conduct at an examination at this early age, when his character is quite unformed and the state of his memory so often depends upon the state of his stomach. Anyone acquainted with boys must know how an insignificant physical cause, such as a headache, bilious attack, or trifling indigestion, will make all the difference; and, what is more, a vigorous, healthy, and altogether superior lad will require a larger amount of air, exercise, and sleep to keep his organs in full physiological play, than another of different physique and temperament, who may be capable on that account of bringing more application to his preparatory work. The Committee, in their report, appear to us to have recognised these things and attempted to provide against them. As regards the army, there are many qualities requisite to make an officer besides book lore. A large number of young men are at present, we believe, undergoing a competitive examination for direct commissions. The army is now a profession to be studied and practised like any other profession, and not to be taken up as a kind of temporary occupation for lazy men whose desire is to get social standing with as little to do as practicable, and it is quite right that they should bring strong brains as well as strong bodies to their work. But we believe that many experienced commanding officers are not at all in love with the new system of officering the army by means of competitive examinations. Where so much turns on the possession of robust health and good physique, it might be well to go further in the competitive direction by classifying the candidates and giving the preference to the strongest in wind and limb. The competitive system is said to answer best for the scientific branches of the service; and the examination for Woolwich is really a test of a man's mental powers, in consequence of mathematics forming so prominent a part of the examination. As far as the Medical Service is concerned, however, the system of competitive examination exists only in name, for the unpopularity of that service has been so great of late—and it is especially so at the present time—that there is no competition; it amounts to a selection of the best men that present themselves.

WE have been waited upon by a deputation from the tradesmen of Sloane-street, with reference to the report of the prevalence of scarlet fever in that street. The deputation assure us that they have made the fullest inquiries, and cannot discover that any case of the fever has occurred in Sloane-street.

Annotations.

"Ne quid nimis."

THE ROYAL COLLEGE OF SURGEONS' ELECTIONS.

The result of the election last week at the Royal College of Surgeons is a matter for general congratulation. It has, indeed, very rarely happened that three candidates so worthy as Mr. Prescott Hewett, Mr. Cooper Forster, and Mr. Birkett, have been elected at the same time members of the Council of the College. The last election declared, moreover, the sentiments of the Fellows of the College. Mr. Hewett and Mr. Birkett were retiring Councillors, but sought re-election, and gained it, thereby receiving the assurance that during their term of office they had not forfeited the confidence of their constituents.

Mr. Cooper Forster, who now takes his seat in the Council for the first time, had so thoroughly gained the good opinion of the Fellows that his return was from the first a matter of almost absolute certainty, as we did not hesitate to affirm. He came forward as a well-known and tried man, and was sure of success. For this reason it would have been well if Mr. Spencer Smith had seen fit to retire altogether from the contest, and the result has shown that such a course would have been prudent. To be elected a member of the Council is certainly an honour of considerable value, but to be the only unsuccessful candidate out of three for re-election can neither serve any useful purpose nor be gratifying to the aspirant. It may be, however, that Mr. Smith and his friends imagined that they had a stronger hold on the Fellows of the College than proved to be the case. That Mr. Smith's friends worked hard for him before the election we have very good reasons for knowing and remembering, and that his friends did not desert him in the day of trouble is very clearly seen by the fact that, out of 97 votes which he gained, 32 were plumpers; while the three successful candidates had altogether only 11 plumpers.

It may not, perhaps, be out of place here to remind the recently elected members that their constituency will regard them with a jealous eye, and that where much has been given much will be required. We are justified, we think, in expecting some more definite action on the part of the College authorities in all the matters that concern the progress of surgery and the advancement of medical education. Nor shall we be deemed too sanguine if we look for greater promptness on the part of the Council in the matter of the Conjoint Scheme, seeing that one-fourth of the present Council of the College consists of members of the Committee of Reference.

THE EPIDEMIC OF MEASLES AT FIJI.

The late outbreak of measles at Fiji seems to have been a somewhat remarkable as well as an unfortunate occurrence—most unfortunate from a humane and political point of view, and remarkable for the rapidity and extent of the spread of the disease. The epidemic appears to have been an extension of that which had been prevailing in Australia. King Cakobau, with some of his family and suite, had been on a visit to that country, where His Majesty had the misfortune to contract the disease. He had recovered, however, by the time he had reached Levuka from Sydney, on the 15th of January last, in H M.S. *Dido*. Of the nature of the disease and of its contagious character there could have been no doubt among the officers, medical or otherwise, on board the *Dido*. According to the interesting account in *The Times*, however, the Fijian authorities, from not having been made aware of the risk of its spreading, adopted no precautions against its doing so. It is possible that the safe return of His Majesty may have been a subject of congratulation, rejoicing, and festivities, and that in this way a large number of native chiefs and others were exposed to the contagion, and afterwards spread it; but there still seems to be considerable room for doubt as to whether there was anything more than an apparent connexion between the arrival of the ship and the outbreak in question. However, the disease, once introduced, spread far and wide. Nor is this the first occurrence of the kind. Dr. Litton Forbes, in his book entitled "Two Years in Fiji," speaks of a similar outbreak among the islanders. A missionary, the Rev. W. Gordon, is said to have been murdered, with his family, by some Erromango men in consequence of the occurrence of a very fatal epidemic of measles having been attributed to his influence. The unfortunate missionary had, it appears, a short time previously to its outbreak, told the islanders that if they did not repent and become converted they would be visited with a pestilence. On the authority of Dr. Litton Forbes's work, we learn that the natives are so depressed and cast down by disease that they may even be regarded as dying occasionally of fright, and in the present instance the inhabitants seem to have been panic-stricken. No sooner did the unfortunate victims of measles suffer from the attendant febrile symptoms than, we are told, they exposed themselves to cold in every way, jumping into the water to cool their bodies. The weather was exceptionally stormy, and from the exposure, and a disregard of proper measures, owing to the conviction that they were being poisoned, the mortality from the epidemic seems to have been enormous. Much sickness still prevails, and it is said that typhoid fever has made its appearance. We hope that medical and every other aid has been forwarded from Sydney, and that the sickness may have entirely disappeared long before the body of Royal Engineers proceeding to Fiji from this country shall have reached their destination.

TREATMENT OF TYPHOID FEVER BY THE COLD BATH.

The recently published Transactions of the Medical Society of the Paris Hospitals contains a suggestive and practical paper on this subject by Dr. H. Libermann. The author, who is surgeon-in-chief of the military hospital of Gros-Caillou, acknowledges that his attention was first drawn to the value of this method of treating typhoid fever by the success with which he had observed it to be pursued in the German ambulances during the war of 1870. He then gives a full historical sketch of the bath treatment of fever, assigning to Currie the honour of its introduction, and giving full credit to the good work done by the German physicians, notably Brand, Ziemssen, and Liebermeister. His own experience has at present extended over twenty cases, two of which were fatal, but he cannot adopt in its entirety the confidence that Brand has in the use of this valuable therapeutic aid. He gives, however, several statistics showing that the death-rate has been considerably reduced by the use of the bath (to nearly one-third of its previous scale), and this from a large number of cases, with deaths from all causes. The most marked reduction, however, has been in those cases which are fatal from the pyrexia itself. The plan of treatment pursued by Brand is now well-known in this country. It consists in the systematic employment of the cold bath (63° to 70° Fahr.) for a time lasting from fifteen to twenty minutes three or four times daily, during which the temperature of the body is reduced from 2° to 7°, the amount of reduction being generally in proportion to the slightness of the case. The warm bath is indicated in cases of extreme nervous prostration, with feebleness of heart's action, or where there is much diarrhœa. The effects of the warm bath are of course not so striking as those of the cold, but both methods are marked by their sedative action on the nervous system, and the disappearance of dichrotism from the pulse. Dr. Libermann then enters fully into the indications and contra-indications for the use of the bath, which he says should be reserved for severe cases—a reservation incompatible with the early adoption (in the first week) of the treatment by Brand, a plan which doubtless has influenced that physician's statistical results. He believes the bath should be employed if, at the end of the first week or the beginning of the second, there is a high evening temperature with but slight morning remission, assigning a temperature of 104° (in rectum) as the usual limit; or if on any one occasion it should reach 105·8°; or if the remissions for days together do not exceed 1°. The bath is contra-indicated in slight cases or in cases complicated with severe diarrhœa or symptoms of perforation of bowel, or where the rise of temperature is obviously due to collateral causes. Pneumonia and hypostatic congestion are benefited by the bath, owing to the improvement effected in the vigour of the heart's action. He appends a few cases, and the whole essay, which is well worthy of perusal, is a gratifying indication that some Frenchmen, at least in medicine, are not slow to learn what is valuable from those who politically are their opponents.

THE FACTORY POPULATION.

DR. FERGUSSON, certifying factory surgeon at Bolton, gave some instructive evidence last week at Manchester, before the Royal Commission appointed to inquire into the working of the Factory and Workshops Acts. Dr. Fergusson has held his appointment for fourteen years, and the result of his observations is that there is a steady degeneration going on among the factory population. He had kept an accurate account of the physical development of all children who came under his notice, and he found that the number of children physically unfit for work went on increasing year by year; of late years, indeed, quite one-half of those submitted for examination were unfit to work full time. This is a depressing account of the Lancashire operatives, but we hope and believe that matters are not quite so bad in other counties. It is often stated that factory labour and factory hours are operating prejudicially on the district population. Dr. Fergusson denies this, and attributes the physical deterioration of the population solely to evil habits. Intemperance, whose wide-spread prevalence in this country is forcing itself on the attention of our legislators, is regarded by Dr. Fergusson as the first cause in debilitating the race, and in transmitting feeble offspring, while a good point was made in condemning the vicious practice now common of rearing children without milk. Dr. Fergusson's statement on this head receives frequent verification in the reports of medical officers of health. It is no uncommon thing in rural districts to find infants fed on coffee and tea, often given them three or four times a day. Another cause given of the degeneracy was the abuse of tobacco. Dr. Fergusson stated that at least one-half of the boys in the mills from twelve to twenty years of age either smoked or chewed tobacco, or both. The injurious effects of tobacco on the young are regularly pointed out in our columns. Happily the abominable practice of chewing—a process in which all the soluble parts of the plant are taken up by the saliva—is rare in this country. The effect of this process on the constitution of a boy is most disastrous. We hope Dr. Fergusson's evidence will be the means of directing the attention of philanthropists and reformers to the condition of the Lancashire factory population. Parliament wisely regulates the age at which boys may commence work, and the hours of their labour, but the measures required to cope with the evils described by Dr. Fergusson are educational and moral.

"LOPSIDED GENERATIONS."

THE ninth volume of the *Journal of Anatomy and Physiology* contains an article by Dr. Hollis with this heading, which gives some interesting particulars as to the history of dexterity. Its prevalence among mankind dates from the earliest biblical records. The ancient bas-reliefs of the Assyrians attest the fact; and anyone who chooses to look over the Kouyunjik gallery of the British Museum will see other proofs, notably in the carvings illustrative of the battle between Assur-Bani Pal and the Susians. The Ancient Greeks were right-handed at a very early period; and the metaphysical use of δεξιὸς, as given by Pindar and other writers, confirms the hypothesis of the prevalence of dexterity in that country. Most if not all languages, on the other hand, have a word signifying "left-handedness," with a meaning closely allied to that of the French *gauche*—i. e., clumsy. Failing to ascertain the origin of right-handedness in post-historic times, the author turns for the clue to the anatomical mechanism of the human body. The larger number of our organs are in duplicate. Those single in man have frequently traces of such duplicate formation (as the nose, brain, heart, and liver). And we know also that our right lung, kidney, liver-lobe, and limbs exceed in size those of the left side; involving, of course, a greater amount of tissue structure, and a larger supply of nerves and blood-vessels for their nutrition. It is known that a person walking in a dense fog figures with his feet the segment of a circle; and that if he is right-handed he takes a direction to the left, because the right leg naturally takes a longer stride. Dexterity appears to be confined to the human race, for the monkey tribes use their right and left limbs indiscriminately in grasping objects given to them. But the differences as to right and left viscera are in many cases greater even than in man, so that this latter circumstance does not conduce to dexterity, though possibly determining in some way the primeval selection of the right hand in man. The left side of the brain is larger than the right; it has been shown that the power of articulation in the right-handed is confined to a certain convolution on the left side; and hence we arrive at the fact that in speaking and thinking we use the left, to the exclusion of the right, side of our brain, this being the result of dextral education. Amnesia and aphasia in right-handed men indicate disease of the left brain; and Brown-Séquard and Ferrier state that this lesion may be removed by exercising the opposite side for articulatory purposes. Hammer palsy (as recorded by Dr. W. Frank-Smith) and writers' cramp (specially commented upon lately by Dr. Poore) show the results of excessive working of the left brain. The author of the paper cites as examples of sacrifice to what he calls this "Moloch of education" the cases of Dr. Johnson, Dean Swift, Spalding (the eminent German scholar), and Dr. Milligan. Brains, in these days of high-pressure speed, break down occasionally perhaps by overwork, but more especially by ill-balanced work; and the obvious deduction drawn and forcibly put before the reader by Dr. Hollis is, that we should "adopt a system of education which will enforce an equal prominence to both sides of the brain in all intellectual operations." Physicians have already learned to relieve the right eye and ear by employing them in turn with the left at the microscope and stethoscope. Why should we not thus educate our hands, and so change Horne Tooke's definition of the left hand as "that which we are taught to *leave out* of use when one hand only is employed," into "that which is *left* for us to use when the right hand is wearied by continued work"?

THE LYON JONES FUND.

IT may probably be known to our readers that a very considerable sum of money—amounting in round figures to £360,000—was left to the Liverpool charities, medical, religious, and general, by the late Mr. Roger Lyon Jones, of that town. Up to the present time the charities have not, however, been benefited by this magnificent bequest; on the contrary, they seem to have occupied the position which a comparatively needy man does to a rich relative. It is a case of great expectations, and it is apt to be forgotten that these do not provide for present requirements. Intending subscribers to the Liverpool hospitals may refuse to put their intentions into practice, and comfort themselves with the assurance that the Lyon Jones Fund will soon be distributed. If we may judge from the *Liverpool Daily Post*, the impression seems to be gaining ground that the executors (who are the sole administrators) intend funding the property and doling out the interest to the different charities. This method of dealing with such a princely sum, and the extent to which the medical charities are likely to be benefited by it, are points at present giving rise to much comment. We think it very necessary that the claims of the medical charities in Liverpool should be distinctly asserted. Certain it is that opportunities are not wanting for doing much substantial good in this direction. The Royal Infirmary is, we believe, considerably in debt, and it is capable of being improved in its construction and arrangements. The Northern Hospital is too small for the requirements of the population amongst which it is situated; and the Infirmary for Ophthalmic cases is quite insufficient as a building to meet the demands made upon it. We adduce these as instances showing that there need be no difficulty in finding directions for doing great and lasting good to local institutions of the most useful and valuable character.

SCARLET FEVER IN SOUTH KENSINGTON.

A SOMEWHAT remarkable outbreak of scarlet fever has excited considerable attention in South Kensington. From the scanty materials at our disposal, it would appear that on or about the 9th ult. a dinner party, followed by an "at home," was given at a house in one of the most fashionable thoroughfares of that very fashionable locality. There had been no illness of any kind in the house previously, and there was no ground to suspect anything wrong in its sanitary condition. Nevertheless, within two or three days afterwards, out of sixteen persons who sat down at the dinner-table, no fewer than six were laid up with scarlatina. More than this, several of the visitors at the reception were similarly affected or attacked with characteristic sore-throat. Nor were the domestics spared, two of them developing the fever shortly after, and other victims of the outbreak suffering from sore-throat. There were, as might be expected, numerous waiters at this party; but we believe no suspicion attaches to them in connexion with the outbreak. Indeed, so far as we can learn, all the facts of the case exclude the idea of personal contagion. The one point which appears to have been clearly made out in the study of the etiology of this outbreak is, that all those who were affected either with primary scarlatina or with sore-throat had partaken of cream in some form or other. Naturally that article would be more largely used at the dinner-table than at the evening reception, and hence the larger proportion of attacks amongst the guests at the dinner. Many persons of course who partook of the cream have escaped, but their immunity may have been due to a variety of causes, and does not furnish an argument against the validity of the *suspicion* that the contagium was carried in the cream. So far scarlatina has not been clearly traced to any person connected with the dairy whence the cream was obtained. The inquiry, however, is still pending, and before long we hope to be able to present our readers with a full account of this remarkable outbreak, which, notwithstanding that it has not proved fatal in any case, has, nevertheless, caused a great deal of distress, and is, in the words of "the medical attendant," "unparalleled in suddenness, variety of age, numbers, and rapidity."

OVERCROWDING IN WATERING-PLACES.

THE overcrowding of watering-places is growing worse year by year in consequence of the increasing throng of visitors at these summer health resorts. It is evident that in many of them no sufficient provision is made for the sudden influx of a transient population, and but slight precautions are taken to prevent dangerous overcrowding. Many seaside villages, whose sanitary arrangements as to drainage and water-supply may be satisfactory and all-sufficient for their usual residents, cease to be true health-resorts when crowded by five times as many visitors. Already watering-place statistics begin to show the results of this overcrowding, and the death-rate from enteric fever in these health resorts, although still low, is highest in the summer quarter of the year, contrary to the experience of other populations. If the sanitary authorities in watering-places neglect much longer to put some check upon the cupidity of lodging-house keepers, and the carelessness of seaside visitors, it will soon be a case of killing the goose for the golden eggs, and the British public will learn for themselves that health will best be preserved by staying at home. There has been a recent attempt to take a census at Blackpool, which appears to have been a failure. The object was probably to ascertain the population of the town when full of visitors, but at a recent meeting of the Census Committee of the Local Board it was stated that large numbers of the enumeration papers had been burned by the householders instead of being filled up and delivered to the collector. It appears that some of the cottage houses had as many as 35 and 40 persons sleeping therein on the census night, and the householders, fearing that the Local Board Commissioners would prosecute them for overcrowding, destroyed their census papers. Whether the Blackpool census prove a failure or not, the Local Board will be wise not to lose sight of this matter of overcrowding.

VERDICTS AT CORONERS' INQUESTS.

THE primary object of holding an inquest is undoubtedly to ascertain the cause of a death, whether it resulted from natural causes or from violence. Before the value of vital statistics was either understood or appreciated, such verdicts as "Death by visitation of God," or "Death from natural causes," or "Accidentally killed," &c. &c., answered all the purposes which inquests were then intended to serve. Now, however, that mortality statistics are turned to increasingly useful account by the expenditure of much time and money, both public and private, such verdicts as these not only cease to be satisfactory, but are decidedly objectionable. Coroners appear too often to lose sight of the fact that the verdict at inquests is entered on the Death Register as the cause of death, and that such verdicts as those we have mentioned are valueless for purposes of classification. About a week since an inmate of Millbank Prison died while undergoing a sentence of seven years' penal servitude. According to custom, although the cause of death was patent to the medical officer of the prison, an inquest was held before Mr. Bedford, one of the Middlesex Coroners. Dr. Munro, the medical officer, gave evidence that deceased when admitted was suffering from tubercular disease of the lungs, and was on this account at once ordered into the prison infirmary, where he died. A post-mortem examination supported this evidence by showing that both lungs were extensively diseased and covered with tubercles. The jury returned a verdict of "Death from natural causes," and the cause of this death will be so entered in the Death Register. Here is an undoubted case of death from phthisis, and had no inquest been held the cause of death would have been so certified by the medical officer; in consequence, however, of this open verdict the cause of the death is in reality "not stated" in the Register. As inquests are held in about six per cent. of the deaths in England and Wales, well-defined verdicts are essential to the value of mortality statistics.

HEALTH OF JERUSALEM.

For more than a year small-pox has been exceedingly prevalent in Jerusalem, Bethlehem, Jaffa, and other towns in Palestine. There are, unfortunately, many native customs and prejudices which militate against a cessation of the epidemic. In the first place vaccination is almost entirely neglected. There is no attempt to isolate small-pox patients, while the sufferers are carefully guarded against the access of fresh air, by which means the atmosphere in the apartments and the clothes of the persons therein become saturated with the poison—thus greatly facilitating the communication of the disease to others. Again, the prejudice against adopting medical treatment for small-pox is almost universal, while the general insanitary condition of the towns and villages is notorious. On the whole the mortality does not seem as great as might have been expected, the disease not having been of a virulent type. But numerous deaths have occurred, and a great many eyes have been destroyed for want of efficient treatment. With the season of early fruits, which are frequently eaten in an unripe state, diarrhœa and cholera have become common in Jerusalem. Some of the cases have been of great severity, accompanied by cold skin and tongue, husky voice, a bluish tinge of countenance, feeble pulse, and cramps of the legs. Desultory attempts at improving the sanitary condition of Jerusalem continue to be made, and the steady influx of Europeans cannot but have a beneficial influence on the health and prosperity of the Holy City.

THE INFLUENCE OF CHLOROFORM ON FERMENTS.

Some important observations have recently been made by M. Muntz on the effect on various ferments of the addition to them of chloroform. He finds that its effect is very different on the two classes of ferments which have been distinguished by Dumas as chemical and physiological ferments. On the former, which consists of a nitrogenised but unorganised material, it has no effect; on the latter, those in which the fermentation is the concomitant, if not the result, of a process of growth in vital organisms, chloroform has the effect of arresting the fermentation at once. Milk, to which a small quantity of chloroform had been added, remained for four months without becoming curdled, and no organism appeared in it; fresh urine, under the same conditions, remained for two months at a temperature of 25° to 30° C. without undergoing ammoniacal fermentation or yielding organisms; the result was the same with flesh, gelatine, and starch. The alcoholic fermentation of sugar in contact with yeast was completely arrested by the presence of chloroform. On the other hand, chloroform had no appreciable effect on the quantity of glucose developed in malt in a given space of time and at a certain temperature. Exactly the same quantity of hydrocyanic acid was formed in bitter almonds with and without the addition of chloroform. Saliva changed sugar into starch at the same rate. Thus this agent offers a means of distinguishing accurately between ferments of the chemical and of the physiological class; and M. Muntz hopes to be able, by its help, to study from a new point of view the nature of the various morbid animal matters which have so disastrous an influence on the economy. At any rate, the effect of chloroform will enable a distinction to be drawn between the forms of animal poison which act in a manner similar to diastase and its analogues, and the altered liquids which are supposed to owe their virulence to the presence of bacteria and vibriones. The influence of chloroform on the organic bodies in arresting all action seems to be transient, but the ferment is afterwards incapable of acting with the same intensity. The lactic acid ferment has a greater power after its recovery from the influence of chloroform than yeast possesses, but prolonged contact with chloroform in each case produces the death of the organisms, and incapacity for further action.

HÆMOSTASIS IN SURGERY.

What shall we do with the arteries after surgical operations? It seems now to be a matter of taste; for, to take only the hospitals of London, it will be found that acupressure, torsion, and the ligature, either with silk or catgut, are severally practised in different institutions. No one will, however, complain that various means should be at hand; it is for the surgeon to decide which is the most appropriate in a given case. Much may depend, however, on whether ischæmia (Esmarch's compression) be used or not. Torsion is a favourite practice in some hospitals; but we have seen abundant secondary hæmorrhage after it, and statistics in this respect are wanting. We are, no doubt, far from the time when hot oil was used; and we may boast of a gigantic stride in regard to hæmostasis, though we are apt, now and then, to fall back upon the practice of our ancestors. And here we have Professor Verneuil, of Paris, who is strongly advising *forci-pressure*, which, as the Professor mentions, was first practised by Desault in 1790. It chiefly consists in the application of forceps with continuous pressure, which may be kept up from twenty-four to forty-eight hours without inconveniencing the patient. The instrument has even been known to remain until it became spontaneously detached. The blades may be smooth or toothed, the latter acting more quickly and, in most cases, successfully. M. Verneuil is convinced that this practice, so long neglected, will not again be so unaccountably abandoned.

ECHINOCOCCUS FLUID.

The chemical composition of the fluid contained in an echinococcus cyst presents so many curious peculiarities that an especial interest attaches to the careful analysis recently made by Dr. Munk of Strasburg. The cyst was situated in the liver. The quantity of solid constituents agreed nearly with that usually found, amounting to 1·574 per cent., of which ·968 was inorganic and ·606 organic matter. The latter contained a distinct trace of albuminate, which has not previously been detected. There had been no inflammation which could account for it. A considerable quantity of grape sugar was present, as Bernard and Lücke had previously found, amounting to ·06 per cent. of the fluid. Dr. Munk suggests that glycogen may be present in the fluid, and transformed by fermentation into sugar after its removal. He could find no glycogen, but the fluid had been drawn off five or six hours before the analysis was made. Urea and kreatin were both detected, and in each case more than a mere trace, but the quantity could not be ascertained. Of the inorganic portion, chloride of sodium constituted about two-thirds (·61 per cent. of the fluid). Traces of lime and magnesia were present, and small quantities of carbonate and sulphate of soda. Only a trace of phosphoric acid was found, probably united with lime and magnesia. No potash could be detected, and the absence of potash and the small quantity of phosphoric acid, both so abundant elsewhere in the body, is very remarkable.

THE TOULOUSE INUNDATIONS.

IF it be true, as the great Italian poet tells us, that there is nothing more painful than the remembrance of happy times amidst affliction, the French people have indeed had much cause of late for sorrow and regret. Whilst only just recovering from the tide of war which had swept over their country, they have had to encounter the effects of this disastrous flood, by which so many have lost their lives, and a far larger number have been rendered homeless. It is needless to say that the suffering has been great, and that this calamity has fallen on France at a time when her people are weighted with a heavy war tax. Under circumstances such as these, acts of international sympathy and help are rightly regarded as a duty; and although we cannot give insertion to some communications that have reached us on this subject, we are glad to call attention to it in the full assurance that assistance will not be withheld by members of the medical profession in carrying out an object like that which the Mansion House Inundations Fund has in view.

PHYSICAL EDUCATION.

MR. BUTLER-JOHNSTONE recently called the attention of the House of Commons to the desirability of introducing physical education into the public elementary schools of this country, and we quite agree with him. We have frequently urged that more might be done in this direction, and with very great advantage to the health and physique of the youth of this country. Too much attention is given to the mental, and too little to the physical, education of the poorer classes, and the consequence is that too many of them, especially those of the manufacturing towns, are stunted in growth, jaded in aspect, and very vulnerable to the exciting causes of constitutional disease. Mr. Butler-Johnstone pointed out that Sweden was the first to adopt this system of education on a sound basis, and that she had been followed by Prussia, and was being followed by Russia, Italy, and Saxony; and we should be glad to add, England.

ABERDEEN UNIVERSITY.

THE Chair of the Practice of Medicine in the University of Aberdeen is vacant by the resignation of Dr. McRobin. The venerable professor retires after a service of no less than 43 years, and will carry with him into private life the good wishes of many old pupils and friends. The vacancy of so important a chair in the practical side of the school will no doubt cause a stir among the physicians of the north. We understand that Dr. Smith-Shand, senior physician and lecturer on Clinical Medicine at the Aberdeen Royal Infirmary, is in the field as a candidate. As the Chair of Midwifery in the same University is still vacant, the filling-up of these two chairs must be a matter of no small concern to those who are interested in strengthening the practical departments of the Aberdeen school. Both chairs are in the gift of the Crown.

THE CONTAGIOUS DISEASES ACTS DEBATE.

THE number of statements of an erroneous character which gain credence from going uncontradicted is probably very large; and the opponents of the Contagious Diseases' Acts have a good deal to answer for in this respect. Sir Harcourt Johnstone, for example, stated the other day in the House of Commons, that "among many surgeons there was a strong feeling against applying these Acts at all, but these officers had been officially informed that their chances of promotion depended upon their willingness to carry out the Acts." As our contemporary the *Broad Arrow* remarks, one would like to see the terms of such an official order. The whole thing is absurd on the face of it. No one has the power to frame any such order, and would not be so silly as to issue it if he had.

THE MEDICAL COUNCIL.

As noticed in a previous number of this journal, the appointment of Mr. Richard Quain as representative of the Royal College of Surgeons of England on the Medical Council will expire on the 14th inst. The following additional vacancies will occur during the present year:—The Apothecaries' Hall, Dublin, represented by Dr. Leet, in August. The University of London, represented by Dr. Storrar, in October. The King and Queen's College of Physicians in Ireland, represented by Dr. Aquilla Smith, during the same month.

DIAGNOSIS IN THE OUT-PATIENT DEPARTMENT.

A CASE of alleged neglect at the Manchester Infirmary is reported. A man who had been thrown by the buffer of an engine against a post was taken to the infirmary. After thirty or forty minutes the junior house-surgeon attended and dressed the patient's head and hip, and told those in charge of him to take him home. The patient died on the way home. It is right to say that he did not seem to wish to stay in the infirmary, though the principal witness, a fellow platelayer who helped to take the deceased to the infirmary, thought he should have been detained. Unfortunately no post-mortem seems to have been made, and the cause of death, though presumably connected with the accident, must remain uncertain. It is to be regretted that the case was not treated more promptly and detained to be watched.

DR. FLEETWOOD CHURCHILL, OF DUBLIN.

THIS well-known obstetrician has resigned practice, and will reside for the future in the North of Ireland. He was President of the College of Physicians in 1867–68, and has presented about one thousand volumes, consisting mostly of works on obstetric medicine and the diseases of children, to the library of that institution. The College have arranged to have a life-size portrait of Dr. Churchill, painted in oil by Mr. Jones, R.H.A., placed in the Examination Hall, and an illuminated address will shortly be presented to him by the Fellows of the College, assuring him of the respect and esteem in which he is regarded by each member of that body.

THE QUEEN'S HOSPITAL, BIRMINGHAM.

A LARGE meeting, presided over by Mr. Sampson Gamgee, was held in the Committee-room of the Town Hall, Birmingham, "to consider the scheme of the Queen's Hospital Committee to abolish subscribers' tickets, charge patients registration fees, and inquire officially into their circumstances." Changes in this direction were strongly denounced by the speakers, especially by Mr. Gamgee, at any rate until further inquiry, and after full consultation with the general body of subscribers and with the committees of the Hospital Sunday and Hospital Saturday Funds. A deputation from the meeting was appointed to attend a special meeting of the governors on the 9th inst.

LYMPHATICS OF THE CHOROID AND RETINA.

This subject has been recently investigated by Morano. He last year announced the discovery of minute perivascular lymphatic channels in the choroid, communicating with the perisclerotic space, and penetrating to the chorio-capillaris; and he has now ascertained the presence of stomata in the pigment layer of the retina (formerly called "choroidal epithelium") similar to the stomata described by Recklinghausen in the serous membranes. These retinal stomata are best marked in the frog, and are mostly formed by the separation of three or four of the epithelial cells; they present internally a curious valvular arrangement due to the presence of three or more small processes from the sides of the orifice, and covered by a delicate endothelium. In mammals they are less constant, and may be destitute of valves, if present.

A parliamentary return obtained by Colonel North has been issued, containing some correspondence which passed between the Lord Chancellor and Dr. Hardwicke in March respecting the proceedings at the inquest upon the body of Sir Charles Lyell. Lord Cairns, after receiving Dr. Hardwicke's explanation of the course he pursued, directed his secretary to state that, while ready to believe that the coroner had acted in the matter under a scrupulous sense of what he considered to be his duty, he "feels obliged to point out to you, as he has done, the considerations which lead him to the conclusion that in a more sound and careful exercise of your discretion you would have adopted a different course, and to express a hope that in future more accurate and reliable information will be obtained before proceeding to public investigations of death, which must be so harrowing to the feelings of relatives and households."

We understand that Captain Webb, who a few days ago swam from London to Gravesend, a distance of twenty miles, is the son of a medical man. Such a feat, performed without any artificial aid whatever, surpasses, in our opinion, Boyton's voyage across the Channel. Captain Webb proposes next month to swim from Dover to Calais, an undertaking that will tax his endurance and stamina to the utmost. There are a few yet living who can recall the profound sensation created in England when Lord Byron, in imitation of Leander, swam across the Hellespont. A humorous print at the time described an imaginary swimming match, in which each competitor started with a huge wallet of provisions strapped to his back. Such conditions of natatory enterprise will probably soon be realised.

The South Durham and Cleveland Medical Society has just published its second annual report. The report is interesting, and a glance at its contents shows that the practitioners of the district take a warm interest in the prosperity of the Society. As the success of a society of this kind depends largely on the industry of its secretaries, we are sure that great credit is due to Drs. Foss and Ellerton.

As Dr. George Wilson, of Paddock, Huddersfield, accompanied by his coachman, was, on the 1st inst., going his usual professional round in a trap, his horse took fright and dashed the vehicle violently against a cart. The doctor was thrown out, and unfortunately sustained a fracture of one of the bones of the arm.

We were under the impression that the authorities at Guildford had lately perfected important sanitary measures and improvements, and had generally put the town in good order. An inhabitant, however, writes to the local newspaper charging the sanitary authority with permitting the sewerage of the borough to remain in a disgraceful state, and alleging that there are numerous cesspools scattered about, which pollute the atmosphere. The writer calls for a complete reform of the system of drainage now prevailing. If the allegations are true, the local board of health has yet a great deal of work before it.

Dr. Iliff, Medical Officer of Health to St. Mary, Newington, has just presented to the vestry nearly 140 volumes on sanitary subjects, including the Registrar-General's printed weekly return of deaths from the year 1856, several valuable Parliamentary Returns, nine volumes of sanitary pamphlets, and a complete analytical index. The vestry, in according their thanks, referred it to the General Purposes Committee to select a suitable permanent place in the Vestry Hall for their preservation.

A recent order of the Local Government Board placing the medical superintendents of the hospitals at Stockwell, Homerton, &c., in the position of general governors, has, in compliance with the wishes of the Metropolitan Asylums Board, been "modified." We suppose that the order has practically been rescinded, and so retaining in the hands of the managers absolute control over the institutions. It is not often that the central authority reconsiders a decision.

The *Army and Navy Gazette* states that Deputy Surgeon-General J. F. Beatson will leave England in the course of a few days to enter upon his new appointment as Surgeon-General, Bengal Medical Service, to which he is to be gazetted on Sir J. C. Brown's retirement, at the end of the year. Dr. Beatson joined the Bengal Medical Department June 16, 1843, and has been Deputy Surgeon-General since April 20, 1869.

Dr. Orme Dudfield, medical officer of health for the Kensington district, in his last report to the Vestry, calls attention to the recent outbreak of scarlet fever in the neighbourhood, which will be found to be dealt with in another column.

The *Portsmouth Times* states that so many cases of fever have lately occurred among the ships of war forming the Channel Squadron that the return of the fleet to Spithead will in all probability be delayed.

Sir William Wilde, of Dublin, has been elected an honorary member of the Royal Academy of Science at Upsala, and a corresponding member of the Geographical Society, Berlin.

We learn that at the recent Dublin Assizes a man was sentenced to five years' penal servitude for causing the death of a child by inoculating it with small-pox.

Last week's mortality returns for the metropolis reveal a considerable increase in the mortality from scarlet fever. Diarrhœa is also shown to be rapidly extending.

We regret to have to announce the death of Mr. J. F. Clarke, M.R.C.S., of Gerrard-street, Soho, at the age of sixty-three years.

Dr. George B. Owens, J.P., has been nominated Lord Mayor of Dublin for next year.

THE DEBATE ON PUERPERAL FEVER.

The discussion on Puerperal Fever at the Obstetrical Society was brought to a close on Wednesday evening last, after having occupied four meetings of the Society. The President, Dr. Priestley, again occupied the chair, and the large attendance of fellows and visitors (including Dr. Fordyce Barker, of New York, and Dr. William Farr) testified to the continued interest taken in the debate. Many doubtless were attracted by the expectation that Dr. Fordyce Barker would address the meeting, and his most able and closely reasoned argument was received with great attention and marks of approbation. The other speakers included Dr. West and Mr. Spencer Wells, who closed the debate. The preliminary proceedings included the announcement by the President of a gift to the Society's museum of certain models of uterine diseases from Dr. Farre; and the exhibition of some interesting specimens by Dr. Stoddard (of Hull), Dr. Newman (of Stamford, who showed a uterus on which Cæsarean section had been performed some years before), and others by Dr. Barnes and Dr. Routh.

A letter was read from Dr. Cordery, of Geneva, containing an account of a case of scarlet fever in an infant, the mother having been exposed to the contagium previous to parturition. The infant died, but the mother did not take the disease. A letter was also read from Dr. Ainsworth, of Ontario, giving an account of a case of measles in a puerperal woman, the disease running its ordinary course.

The President having called upon Dr. Fordyce Barker, that gentleman began by stating that it could not be supposed that anyone could answer in the affirmative all the questions propounded by Mr. Wells; for if some were accepted, others must be rejected. That a special morbid poison does not always give rise to the same disease he instanced by quoting cases of "typho-malarial" fever and diphtheria arising under the same conditions—viz., escape of sewer air into the house. Criticising the case quoted by Dr. Playfair of septicæmia occurring in a puerperal woman whose husband was at the time ill with diphtheria, he said that it was implied that identity of cause must always be followed by identity of result. He believed, however, that puerperal fever was a *distinct* disease, and thought the definition contained in the "Nomenclature of Diseases" was an accurate one. To ascertain the truth of his statement as to puerperal fever being a disease peculiar to the puerperal state, it must be studied as to its causes, its clinical features, and its pathological characters. With regard to the causes, he thought that there was abundant evidence from the study of epidemics that whereas the prevalence of scarlet fever, typhoid, or the other contagious fevers does not give rise to puerperal fever, yet there is a certain relation between erysipelas and puerperal fever; for erysipelas will give rise to this fever in lying-in women, and the puerperal poison will develop erysipelas in men. It is possible that a septic poison acting on the peculiar state of the puerperal woman would give rise to a disease distinct from that produced by the same poison in any other condition of body. The clinical facts bear this out, since septic poisoning never gives rise to an epidemic when it appears among surgical cases, while if it attack a woman after childbirth, it does become epidemic, and is highly contagious; and that puerperal fever is epidemic he showed by quoting statistics of the prevalence of that disease in certain quarters in New York, for a certain time, under insanitary conditions. The clinical phenomena of puerperal fever are quite different from those of surgical septicæmia and pyæmia, and when these affections complicate puerperal fever they modify its symptoms. As to the pathological features of puerperal fever, he maintained that few, if any, uncomplicated cases of the disease had been studied pathologically, and it would be nothing strange if there were no distinctive lesions met with, for what are the distinctive (post-mortem) lesions of the exanthemata? He thought, then, on clinical grounds chiefly, that the term "puerperal fever" should be retained, as signifying a specific affection peculiar to the puerperal state; and in conclusion, he quoted the saying of Oliver Cromwell: "I beseech you, by the mercies of God, conceive it possible that you may be mistaken."

Dr. West, referring to the question as to the presence of organisms in connexion with the disease, thought that question was premature with regard to puerperal fever, seeing how much at variance were observers as to their occurrence in other better known diseases. He thought but little had been added to our knowledge of puerperal fever since Dr. Ferguson, thirty-six years ago, taught that it consisted in a "vitiated state of the fluids;" and he pointed out how much the affection wanted the characteristics of a specific fever, as to its cause, its multiformity, its origin from many sources, &c. The disease received its special characters simply from its arising in a special state of the system, in which retention of effete matter was the chief factor.

Dr. Snow Beck then read a long statement of his belief that puerperal fever was not a disease *sui generis*, and that it might arise from general or from uterine causes. He advocated, therefore, the removal of the term from the nosology.

Mr. Green gave the results of his experience in a large number of cases of puerperal fever, arising from decomposing clots, contamination from attendants, scarlet fever, small-pox, erysipelas, and typhoid; and concluded that there was no specificity about the disease.

Dr. Routh stated that he was present at Vienna in 1846–47 during the time of the memorable outbreak of puerperal fever in the hospital there, and he gave some interesting details concerning this outbreak, which was clearly proved to be due to carelessness on the part of students attending the dissecting-rooms and dead-house. At this epidemic it was distinctly made out that the disease was *not* contagious from one woman to another, save by inoculation; also, that the infants born of the affected patients all died of peritonitis. But there is doubtless another variety of puerperal fever, which is eminently contagious, and this form arises from the poison of scarlet fever &c.

Dr. Hill quoted his recent experience of some cases of puerperal fever of pyæmic origin which were not contagious, while others which followed exposure to typhoid poison were eminently so.

A Member read a long statement, the main drift of which appeared to be an attempt to show the identity of scarlatinal, typhoid, and puerperal poisons.

A communication from Dr. Holman, of Reigate, was taken as read.

Mr. Spencer Wells then replied. He said he would go beyond Dr. Barker's position, and affirm that a specific morbid poison must always produce the same result. If puerperal fever be a distinct disease, its specific cause must be shown. The Registrar-General had furnished him with the statistics of an outbreak of puerperal fever in South London two weeks ago, in which three cases, attended by one practitioner, were fatal, but two others did not take the disease. Scarlet fever was very prevalent in that district, and it would be interesting to know if the two women who escaped had previously had scarlet fever. Mr. Wells also read extracts from several letters he had received of cases of scarlet fever, erysipelas, and typhoid giving rise to puerperal fever; and also an important letter from Dr. Keith, of Edinburgh, in which the connexion between puerperal fever, pyæmia, and erysipelas was strikingly shown occurring in connexion with some recent operations of ovariotomy performed by that gentleman. In conclusion, Mr. Wells deprecated strongly the attempt that had been made to enlist the sympathy of the Society on behalf of those midwives who had recently (through their wilful disregard of caution given them by medical men) been guilty of "homicide by infection"; and he thought that far more good would be done by inculcating the necessity of taking extra precautions, even to giving up practice for a time, so as not to endanger the life of one puerperal woman.

The meeting then adjourned. A full report will appear in our next issue.

STATE MEDICINE.

SURGEON-MAJOR DU CHAUMONT'S concluding lecture at Apothecaries' Hall was delivered on Saturday, June 19th, and was devoted to a consideration of the prevention and propagation of disease, epidemics, and the value of statistics relating to sanitary questions.

It is obvious, observed the lecturer, that the efficacy of the methods employed for the prevention of disease depends upon our knowledge of its origin and modes of propagation, and, failing such knowledge, upon the view or theory which is held. Thus a disbeliever in contagion would probably think isolation unnecessary, while a man who rejected the possibility of water conveying disease would look with indifference upon the pollution of the water-supply. On the whole, however, we find that whatever view may be held about the actual *modus operandi* of disease, all persons are substantially agreed that general unhygienic conditions are favourable to it; and it must be admitted that if such conditions can be avoided more than half the battle will be won. But there is still something beyond, and we must view the possibility of the introduction of morbific poison even when purity and plenty are attained in the matter of air and water. Let it be granted that there is such a thing as a communicable *materies morbi*, and the question is then reducible into disinfection and isolation.

The object of disinfection is to destroy the morbific poison, or to suspend its action if its destruction cannot be accomplished. The destruction may be effected by airing, by certain chemical agents, or by wet or dry heat. The first method, that of exposure to air, is slow and uncertain. The chemical agents used in disinfecting are chlorine, nitrous acid, sulphurous acid, chromic acid, and the permanganates, the first three being available for fumigation. However, the best method of destroying morbific poison is exposure to heat. Boiling is very efficacious, but steam under pressure, or a gas-disinfecting chamber, is still better. A dry heat of 230° Fahr. effects the object without charring clothes. A disinfecting chamber ought to be provided and made readily accessible in every district or town, so that there might be no excuse for allowing infected bedding to lie about. The activity of morbific poisons may be suspended by extreme cold, or by carbolic acid, and certain other vegetable products, but these agents do not destroy the poison. Minute organisms, such as monads and bacteria, cease to move or reproduce in the presence of such substances, and there is a singular absence of life in tarry water. The most important application of this fact is the well-known antiseptic method of Professor Bristowe.

Thorough cleansing and fumigation ought to be carried out even in the case of diseases not looked upon as contagious. Care should be taken to provide as few resting-places as possible for morbific poisons; yet so little is this considered that we often find bed-curtains and window-curtains even in hospitals. Stools ought to be disinfected, and the sick room carefully dusted; for the emanations from the skin in small-pox, scarlatina, and measles may be disturbed, and find a new and appropriate nidus after a considerable period of rest.

As to isolation, it is next to impossible in ordinary dwellings, and therefore adequate means for securing it ought to be provided by the sanitary authority. The importation of a single case of disease is often enough to light up an epidemic. The question of quarantine is a difficult one; but, no doubt, if quarantine could be effectually carried out it would check the spread of disease.

There is one special branch of isolation of great interest and importance, and that is the prevention of venereal disease under the Contagious Diseases Acts, which apply to seaport and garrison towns. Similar measures have been in operation on the Continent for many years, the result being that syphilis was much less frequent there than in our own country before the passing of the Acts. In Malta an Act of the same kind has been long in vogue, under our own Government. A temporary suspension of the Act in Malta took place about sixteen years ago, and this suspension was followed by an increase of the disease. A similar Act has been enforced in Calcutta with excellent results, although its application was a matter of great difficulty. In spite of what has been written against the Acts in this country, it can be safely asserted that their operation has been decidedly beneficial. It is only necessary to turn to the army and navy returns to see the necessity of legislative measures on the subject. Returns compiled by Dr. Stewart Balfour show that before the passing of the Acts about one-fourth of all the cases of disease admitted consisted of primary venereal sores and gonorrhœa. The returns for Portsmouth showed 503 cases per 1000 admissions in 1860, and 485 in 1861. Reckoning the value of a soldier's services at £100 a year, the loss of service from enthetic diseases amounts to about £221,000 a year, without including the loss from diseases aggravated or influenced by the venereal class. The testimony of the dead-house at Netley is grimly significant, hardly a body being opened there which does not show traces of syphilitic influence. The diseases influenced or aggravated by this means are chiefly those of the heart and great vessels, of the cerebro-spinal system, phthisis, rheumatism, ophthalmia, and skin diseases. Could we stamp out syphilis we should reduce sickness in the army and navy by one half. In the Crimea, where the possibility of venereal disease was eliminated, sickness almost entirely disappeared.

The lecturer then dwelt at considerable length on the objections which are generally urged against the Acts. In answer to the statement that the action of the legislation tended even to increase the prevalence of the disease, he compared two groups of stations of about the same numerical strength, in only one of which the Acts had been enforced. In that group where the Acts had operated, there had been a well-marked decline in the number of cases since 1866, when the second and more complete law was passed, as compared with the previous period, although there had been fluctuations, as there always must be as long as the disease exists. In the group which had never been under the Acts, there appeared to be no tendency whatever in the disease to die out. As to the assumed immorality of the Acts, he contended that prostitution is no more provided for now than it was formerly; but the Legislature, having recognised the existence of an evil, has taken means to check it, and thus avert from the community the burden which would be entailed by the infirmity of the sufferers themselves, and the vitiation of their innocent offspring. Those who object to the requisite examination must be very innocent or very disingenuous if they really think that it can have a demoralising effect upon the loose women who are the associates of soldiers and sailors. In answer to those who say that the disease is sent as a punishment for sin, and therefore ought to be left to take its course, the lecturer pertinently asked, in the words of the great Master, "Were those on whom the Tower in Siloam fell sinners above all others?"

As to the origin of disease in general, we are still as far as ever from any real knowledge of it. The vexed question of the existence of germs of disease, or the propagation of disease *de novo*, deserves attention. The majority of observers are in favour of the view that there is a special poison which produces a particular disease, and the evidence supports this idea. Again, it has been urged that the doctrine of evolution may be applied to material organisms;

but at no time does the doctrine of evolution ever contemplate the direct change of one organism into another; and another important part of the doctrine is, that when organisms become determinate in a particular direction and reach a high state of perfection, their chances of evolution become lessened if not nullified. It would seem, on the other hand, that when the limit of integration is reached the type tends to decay. It may be thus with the germs of disease, and, probably, from their low type of life, the limit is soon reached. Thus it is not improbable that some diseases will disappear altogether from sheer decay before we are able to discover their nature, or we may stamp them out before they have time to decay.

The theory of the spontaneous origin of disease supposes that a disease may be produced from organic germs different from itself, and that these germs may arise directly from combinations of inorganic matter. The advocates of this view, however, among whom Bastian is one of the most noted, can hardly have understood the tremendous nature of the postulates they demand. The simplest process of chemistry, such as the formation of a drop of water from its constituent gases, requires as much force as would furnish a flash of lightning; and yet we have people who ask us to believe that creatures as high in the scale as paramecia, and even acari, can arise spontaneously.

In treating of the subject of epidemics, the lecturer mentioned the recent paper of Dr. Tripe, in which he states that his investigations as to scarlatina seem to point to the existence of periodic waves of disease. If, as Dr. Tripe concludes, scarlatina, like other diseases, is controlled by influences which are not within the scope of ordinary hygienic means, we cannot hope to stamp it out, but must only expect to modify it by care. It may be, however, that the apparent periodicity of certain diseases arises from the fact of a severe epidemic exhausting the supply of susceptible individuals.

The scientific history of epidemics has still to be written, but good work is being done in that direction. The science of statistics must be at the base of all inquiries on the subject, and ought to be more generally taught. A proper attention to it would prevent crude generalisations from insufficient data. When facts are honestly collected and sufficiently numerous, averages give a very fair approximation to the truth.

In concluding his discourse the lecturer expressed a hope that he had been successful, however imperfectly, in putting before his hearers reasons for believing that there was a great future for sanitation, and that, if the State did its duty, this subject must be hereafter one of its chief cares.

CHARING-CROSS HOSPITAL.

THE annual distribution of prizes took place in the Board-room of the hospital on the 24th ultimo, the chair being ably filled by Admiral Strange, a governor of the hospital, and one of its warmest supporters.

The report, which was presented by Mr. Hird, the Dean, alluded to many matters which were subjects for congratulation. The arrangements for teaching had been greatly improved by the opening of a fine new suite of Physiological laboratories; the opening of two new wards offered a wider field than heretofore for clinical study; the library had been enriched by a gift of over two hundred valuable books from Mr. Hancock; and the system of test examinations, which had been lately instituted, had borne good fruit, in an unusual amount of success attained by the students at the College and other examinations. That these various points were appreciated was evidenced by the fact that during the past year fifty new students had attended the various courses of lectures.

The following is the prize-list for the year:—

JUNE 24TH, 1875.—Llewellyn Scholarship, Mr. P. B. Conolly; Governors' Clinical Gold Medal, Mr. Walter J. Brookes. Anatomy, Senior (Silver Medal), Mr. Arthur Greenwood; Certificates, Mr. D. Colquhoun, Mr. Hayward Whitehead, and Mr. F. S. Boreham. Anatomy, Junior (Bronze Medal), Mr. H. Hoole; Certificates, Mr. Sidney F. Newton and Mr. A. D. Leahy. Physiology, Senior (Silver Medal), Mr. D. Colquhoun; Certificates, Mr. Hayward Whitehead and Mr. J. L. Robertson. Physiology, Junior (Bronze Medal), Mr. H. Hoole; Certificates, Mr. Sydney F. Newton and Mr. A. D. Leahy. Chemistry (Silver Medal), Mr. H. Hoole. Medicine Senior (Silver Medal), Mr. Walter J. Brookes; Certificates, Mr. E. Manby Rodwell, Mr. Herbert Packer, and Mr. P. B. Conolly. Medicine, Junior (Bronze Medal), Mr. D. Colquhoun; Certificates, Mr. Hayward Whitehead and Mr. Arthur Greenwood. Surgery Senior (Silver Medal), Mr. P. B. Conolly; Certificates, Mr. Herbert Packer and Mr. J. A. Phillips. Surgery, Junior (Bronze Medal), Mr. D. Colquhoun; Certificates, Mr. Hayward Whitehead and Mr. Arthur Greenwood.

SUMMER SESSION, 1874.—Botany (Silver Medal), Mr. Sidney L. Newton; Certificates, Mr. D. Colquhoun and Mr. Arthur Greenwood. Materia Medica (Certificate), Mr. W. B. Hodgson. Midwifery (Certificate), Mr. P. B. Conolly. Forensic Medicine (Silver Medal), Mr. Walter J. Brookes; Certificate, Mr. D. S. E. Bain. Pathology (Silver Medal), Mr. Walter J. Brookes; Certificate, Mr. J. G. Blackman. Practical Chemistry (Silver Medal), Mr. D. Colquhoun; Certificates, Mr. Arthur Greenwood, Mr. Hayward Whitehead, and Mr. Sidney L. Newton. Psychological Medicine Prizes, Mr. P. B. Conolly and Mr. D. S. E. Bain.

The prizes having been awarded, the gallant Admiral made a most eloquent and feeling address to the students, and the proceedings terminated by the usual vote of thanks, which was proposed by Dr. Fayrer, one of the most distinguished *alumni* of the school, and carried by acclamation.

THE BRITISH MEDICAL ASSOCIATION.

THE final arrangements have been completed for holding the 43rd annual meeting of this Association at Edinburgh the first week in August, Sir Robert Christison, M.D., being the President elect. On the first day, Tuesday, the 3rd of August, the first general meeting of members will be held, at which the President will deliver an address; the annual report of the Council will also be given at this meeting. In the evening a reception will be given in the University Library. On Wednesday the second general meeting will be held, at which the Address in Medicine will be given by James Warburton Begbie, M.D., F.R.C.P., Edinburgh. In the evening a conversazione will be given by the Royal College of Physicians of Edinburgh. On Thursday the third general meeting will be held, at which the Address in Surgery will be given by Professor James Spence. In the evening the annual dinner of the Association will be held. On Friday, the last day, the Address in Physiology will be given by Professor Rutherford, and the concluding general meeting will be held.

"Audi alteram partem."

ELECTION OF THE COUNCIL AT THE ROYAL COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—The last election at the Royal College of Surgeons has revealed a widespread discontent amongst the Fellows.

It is assumed that the members of the Council are elected by the Fellows at large, but the election takes place at the College in London, whilst the majority of the electors reside in the country hundreds of miles distant, so that it is not possible that any election can represent the opinions of the general body.

It is a mere mockery of justice to bestow a franchise on Fellows which in so many cases they cannot possibly use, because they are unable to leave their duties, and incur the cost, the loss of time, and fatigue of the journey, simply to enable them to drop a voting paper into a ballot box.

Every man entrusted with a vote is bound to have a *bonâ fide* opportunity of recording it; for if he has not, he is virtually disenfranchised. For this reason Parliament has wisely decreed that the members of universities who are in a similar position with respect to residence to the Fellows of the Royal College of Surgeons can vote by papers without the necessity of a journey. By the Act 24 and 25 Vic., cap. 53, the members of the universities of Oxford, Cambridge, and Dublin, are empowered to employ voting papers. This privilege was extended to members of the London University by 30 and 31 Vic., cap. 102, and the details of election were further simplified by 31 and 32 Vic., cap. 65.

The College of Surgeons, having been shown the way, has only to take advantage of the precedent by procuring an Act of a few lines in length, rehearsing the University Election Acts, and applying their provisions to the particular case of the College of Surgeons before the next election can take place. The question has only to be raised for its propriety to be admitted, for where is the surgeon who would not rather watch a serious case where life or death may depend, than neglect his patient that he may formally hand over a printed paper to the recognised official of the College of Surgeons?

To obtain the desired end proper means must be taken. The body of country Fellows must ask before their request can be granted, and I shall be glad to receive the names of every Fellow desirous of voting by papers, that we may at once take steps to obtain the Act of Parliament necessary to obtain our just due.

I remain, Sir, your obedient servant,

Finsbury-circus, July 6th, 1875. ALFRED SMEE.

P.S.—Only fifty-seven country members could vote at the late election.

THE MEDICAL COUNCIL AND THE REGISTRATION TAX.

To the Editor of THE LANCET.

SIR,—The profession in general will thank you for your criticism on the Medical Council and its listless apathy toward the practitioners of this country, whom it is supposed to represent and to protect. A short time ago you published the stereotyped answer which the Council presented to all those who applied for its aid. I confess that this answer is sufficient to raise strong feelings of indignation in the breast of anyone who has been mulcted of the £5 5*s*. fine for having his name placed on the Medical Register. We feel, and I think no impartial person can be surprised at it, that we do not get a *quid pro quo*. We derive no commensurate advantage from having our names on the Register. If our rights or privileges are invaded, the august Council folds its arms, saying, "Really, my dear sir, I have pocketed your money, what further business *can* I have with you; but, 'pon honour, you know, if I were in your place I should prosecute the fellow." Then their tax is most undoubtedly a *cruel* one. Often when a man has just taken his qualifications, the heavy fees, &c., have left his pocket by no means well lined. Then, before he can take, or even become an eligible candidate for, any official appointment, he is obliged to pay his £5 5*s*. to the Medical Council, and I can affirm that most "grudgingly and of necessity" is the said fee always paid. Moreover, it is a most decided case of taxation without representation. We, the body of general practitioners of the United Kingdom, are not represented in the Council at all. Taxation without representation has always been recognised as a grave political error. It lost to this country America. I live in hopes that it may yet lose to our profession the General Medical Council. For my own part, I regret to say that I have often spent money foolishly, but never, even when I lost it in horse-dealing, or backed a "certainty" which "didn't come off," did I feel so utterly *done* as when I paid five pounds five shillings to enrol my name on the Medical Register.

One word more. If I venture to change my residence without giving due notice to this august body, I am liable to be removed from the Register. If Mr. So-and-so is committed to prison as a felon and vagabond, he is liable to be removed from the Register, and so far as I can see it makes little or no difference to either of us. Mr. So-and-so and myself may both retain our qualifications and practice, and the Medical Council has no further power over us; but it is flattering to a man of unblemished honour to place him in the same category as a convicted felon. Verily the code of the Medical Council is that of Draco, and death is its only punishment, with this difference, that "death" at the hands of the Medical Council seems very harmless.

I am, Sir, obediently yours,

NON PLACET.

PRIMARY EXAMINATION FOR THE FELLOWSHIP OF THE COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—I am glad to find that the letter which I wrote to you on the 5th ult. has induced some other members of the profession to publish their opinions of this examination. I shall not trouble you with any remarks as to whether the qualification should be a test of larger acquirements from students, or merely an improvement of the professional status of the practitioner, although I cannot see why both might not be combined to the great advantage of the profession, instead of neither being satisfactorily attained, as at present.

I would again insist on the *uncertainty* of the examination as now conducted, and I am corroborated therein by all who have written to you on the subject. The limitation of time at the *vivâ voce* and the details of marking are evidently unfair, and I am glad to find that the former has been pointed out by the visitors as a blot on the Primary Examination for the Membership.

Mr. Macnamara is undoubtedly a most competent judge of the examination, and he in the main agrees with me. Whether four questions only on such wide subjects are preferable to a larger number is a matter of opinion, but it must be remembered that the Fellowship is a *pass*, and not a *competitive*, examination, and therefore that no opportunity of discovering how much a man really knows should be omitted.

I perceive that the visitors to the various examining bodies have pointed out to several of them that the number and extent of their questions are insufficient, and I have little doubt but that they will come to the same conclusion when they visit this examination.

May I venture to recommend to the authorities of the College as model examination papers in Anatomy, Physiology, and Comparative Anatomy (should they decide to include the last subject), those set during the past few years by the examiners for the Second M.B. at the University of Cambridge?

I am, Sir, yours very faithfully,

July 5th, 1875. W.

OVERWORK.

To the Editor of THE LANCET.

SIR,—I have recently had under my own eye a case remarkably illustrative of the views propounded by Dr. Wilks in his interesting letter last week on Overwork.

Between two and three years ago a "delicate" young lady, eighteen years of age, was cooped up in a luxurious home, her parents believing her to be the subject of heart disease. She certainly suffered at intervals distressing paroxysms of neuralgic pain, chiefly in the left temporal region, but sometimes also over a small space below the left breast, and she had a slight nervous movement of the fingers, I forget now whether of one hand only or of both; I think of both.

The life of this young creature was being partly wasted in general invalidism, as she was not allowed to exert herself in any way whatever, or to have any social excitement, and partly spent in the endurance of acute agony, sometimes lasting for hours. Happily, however, she became a temporary resident in a school where, under medical direction, all this was changed.

A sedative was administered when needful to secure sleep, but the treatment was chiefly hygienic. She was encouraged to rise between seven and eight, to take easy walks, to pursue courses of study, and now and then to attend a concert, and after a while she began to ride on horseback, and to dance.

The result of this aim to develop natural energy has proved all that could be desired. By degrees the neuralgia has quite passed away, all invalid habits have been cast off, and my young friend has for the last twelve months been as bright and active a girl as you could wish to see. I am persuaded that the plan of recommending young ladies, when they complain of headache and depression (most likely resulting from dyspepsia dependent on errors in diet), to discontinue mental exertion, and to become idle, is a great mistake. Supposing the absence of organic disease, sufficient out-door exercise in good air, simple, nutritious, regular food, and early sleep, with a fair supply of oxygen at night, no harm can come of hard work by body or mind. I have been a toiler for thirty-five years, and enjoy perfect health, although it has never been my habit to rest except when asleep.

I am, Sir, yours, &c.,

June 28th, 1875. M.D.

CATHETER STAFFS.

To the Editor of THE LANCET.

SIR,—Allow me to inform Mr. Teevan that the first surgeon who employed a staff with a sliding catheter for perineal section was the late Dr. Mackenzie, of the Royal Infirmary, Edinburgh, who used it in the year 1854 (*vide* THE LANCET, vol. i. 1857, page 282).

I remain, Sir, your obedient servant,

Surrey-street, July, 5th, 1875. R. WILLIAM DUNN.

BIRMINGHAM.

(From our own Correspondent.)

A SPECIAL Committee of Investigation has been deliberating for some months on the general system of administration of the Queen's Hospital with a view of ascertaining the means by which a balance between income and expenditure may be effected. A report has just been issued by the committee, which will be submitted to the governors on the 11th inst. This report contains the following recommendations: "The abolition of the privileged system, the cessation of notes, and the working of the hospital on the basis of free admission, regulated solely by the needs and fitness of the applicants and by the means at the disposal of the charity." In conjunction with this scheme they propose, except for accidents and urgent cases, a registration fee of one shilling for each patient, such fee to be renewed at the expiration of a month. Much excitement has arisen, and not a little opposition is being shown to the adoption of the free system by some of the subscribers and by the working classes, while the registration fee is also condemned by a majority of the staff of the hospital. The free system is justly allowed to possess the merit of giving absolute freedom to the medical staff in deciding as to the medical fitness of applicants for relief, and is no doubt the simplest and most effectual way of working this or any other hospital. The registration fee, however, had better be given up; it is no integral part of the free system, but, on the contrary, it will be looked upon by many of the artisan class as a direct payment for medical attendance, and will therefore render the hospital unpopular with them, and it will also alienate a large number of the medical profession, who already believe that the hospital attends to many patients who could well afford to pay them a fair sum for their advice. The ticket system cannot be with propriety continued, for it is evidently not effective, and is not appreciated by the governors. During 1874, out of 1863 in-patients who were admitted, only 345 were admitted by ticket, and 1338 were admitted free, while of the out-patients nearly one-half were attended to without tickets. The registration fees on the number of patients treated in 1874 would produce £847, a sum quite inadequate to cover the estimated deficit for the ensuing year, which is set down at £1718. As, however, some of the artisans and middle-class subscribers will very likely withdraw their subscriptions should this plan be adopted, there will ultimately be rather a loss than a gain to the hospital from its adoption.

Four applications have been sent in for the office of coroner, two by members of the medical and two by members of the legal profession. One of the latter, Mr. Alderman Hawkes, a sexagenarian who is known as the Nestor of the so-called Liberal party in Birmingham, will no doubt be elected, as a majority of the corporation absolutely invited Mr. Hawkes to become a candidate directly the office was declared vacant, and promised him their support even before they knew who had or even who were likely to come forward for the appointment. Several medical practitioners of good standing, among them the present medical officer of health for Birmingham, would have become candidates, but they very wisely and properly withdrew when they found that the invitation to send in applications and testimonials was all a farce, and that the appointment of Mr. Hawkes, as a reward for political services to the Liberal party, was already a *fait accompli*.

Wolverhampton is not to have a park after all. The Mayor has done his best to promote the interest of his fellow-townsmen, but the parsimony and narrow-mindedness of the great majority of the Town Council have prevented the proposed purchase of the park out of the rates.

Dr. Ballard thought that Sedgley was the most unwholesome town in the Black Country, when he examined it, but the palm is now awarded by him to Oldbury. He describes the place as utterly devoid of drainage, the solids and sewage lying about on all sides, impregnating the water-supply, and filtering in many places into the houses. He finds that only 1172 out of 3475 houses receive the company's water, and that the rest depend on surface wells, all of which are more or less polluted; as a natural result the death-rate has risen from 22 to 28 per 1000, and out of the total deaths in some parts of the town during the last five years, more than 50 per 1000 have arisen from zymotic diseases. The Local Board, although censured by Dr. Thorne for a similar condition of things four years ago, did nothing but appoint an officer of health at the munificent salary of £30 per annum, and channel a few of the streets. Dr. Ballard has informed the Local Board that if steps are not at once taken to remedy the present insanitary state of the town, the Government will compulsorily carry out the necessary reforms.

Birmingham, July 4th, 1875.

Obituary.

M. DEMARQUAY.

DEMARQUAY, whose death we announced with regret in our last issue, was one of the most active, laborious, and inventive French surgeons of the day. Through his elaborate productions, as well as his valuable additions to practical surgery, he had won for himself a distinguished and enviable name in surgery, not only in his own country, but wherever surgery is studied and practised.

He was of most humble origin. He literally rose from the ranks, and by dint of strong will, unflinching purpose, and hard work, after having been compelled to take various occupations for a livelihood, he attained one of the highest scientific and professional positions in Paris. About forty years ago he left his father's house at Longueval, in Somme, with the intention of following some manual trade, and two weeks before his death he quitted Paris, where he had become rich, popular, and esteemed, to go and die in his native place, on a large estate which he had bought when wealth had come with reputation and honour.

His scientific titles, his various additions to practical surgery, his numerous inventions and modification of modes of operating, or of surgical contrivances, would be too long to mention in this short necrological notice. The most widely known of his elaborate works of surgery are those on Glycerine, Surgical Pneumatose, Renovation of Tissue, and his complete and interesting relation of the working of the Ambulances of the Press during the Paris siege. But these are only a few of his literary productions. Demarquay was an incessant writer. His communications to the Paris medical press, to the Academy of Sciences and that of Medicine, were most frequent; and they all bore the stamp of great quickness of intellect, keenness of inquiry, and an inventive and practical turn of mind.

His activity in all the other paths or duties of his professional life was quite as great. Every morning at the Maison Municipale he was most busily engaged in his wards, speaking or giving short clinical lectures at the patients' bedside to the large number of pupils, medical journalists, and foreign *confrères* who attended his visits. His labours in his surgical laboratory and lecture-room, which he had had built up and organised for himself at the hospice, were constant. In this small laboratory there was always something new going on. Some question of the day to be investigated; some subject of physiological surgery to be experimented on; some surgical specimens to be shown. The remainder of the day was taken up by the urgent duties of his extensive *clientèle*, consultations at home, visits and operations in town. His evenings were devoted to study, literary writing, or social parties, in or out of his house, which were always very frequent. Demarquay loved to receive his friends in his splendid apartments in the Rue Taitbout.

His great popularity was due not only to his intrinsic worth, his kindness to hospital and town patients, but also to his special connexion with the Maison Dubois, to which he was attached for years as head surgeon. This hospice, though under the same administration as the other Paris hospitals, only receives patients who can pay, and it is the great resort of the artists and literary characters of Paris when the hour of illness comes. Thus Demarquay had a wide circle of grateful literary friends, who contributed much to make his name popular.

Many anecdotes are related of his generosity to his poorer patients. He had a peculiar, blunt, genial way of doing good; a kind, authoritative paternal bearing to the inmates of his hospital. He was of tall stature, rather bulky, but of commanding appearance, with a large round face, high forehead, frizzled hair, and pale, freckled complexion. His health, which had always been very robust, seemed to fail some time ago, and he would complain of weakness in the stomach; but no one scarcely suspected the possibility of a cancer, which so soon carried him off. He was not a brilliant operator, in the sense of nimbleness of fingers and elegance of touch; but he was steady, careful, and inventive.

He was a member of the Academy of Medicine, and also of the Paris Society of Surgery, which, at its last meeting, unanimously declared the sitting adjourned when the President announced Demarquay's death.

He was a bosom friend of Ricord—his *alter ego*, his *inséparable*. Their friendship had sprung up and grown strong, under trying circumstances, during days of work, grief, and danger, when they both had the ambulances of the press under their direction during the siege, and did their duty together on the battle-fields round Paris. Since then they were inseparable. Their names almost always came together before the public. They went out for their holiday excursions to distant places, to Constantinople and the East, and published their travelling impressions in the racy, witty, lively style peculiar to both of them. More than once they came together to England, as will be remembered with mingled pleasure and regret by those who saw them in London after the war, and in Birmingham at the Association meeting of 1874.

THE PROFESSORSHIPS AT THE ROYAL COLLEGE OF SURGEONS.

ON Thursday last the Council of the Royal College of Surgeons elected the professors and the lecturer for the year. Mr. Erasmus Wilson was re-elected to the professorship of Dermatology, which, it will be remembered, he himself created in 1869, and which he has since continued to monopolise, to the detriment of younger members of the profession, who naturally desire the honour of occupying that chair, and whose ambition it would be to fill it worthily. Mr. Parker was reappointed to the Hunterian professorship of Comparative Anatomy and Physiology; Mr. Turner, of Edinburgh, was again appointed the Arris and Gale lecturer on Anatomy and Physiology, but will in the ensuing year be associated with Mr. Flower, who, we are glad to find, is sufficiently recovered to undertake his duties at the College.

But the most important professorship at the College, as far as the great body of the profession is concerned, is of course the Hunterian Professorship of Surgery and Pathology, and this year the appointment is of exceptional interest, inasmuch as a new principle is involved. The successor to Mr. Henry Lee, of St. George's Hospital, is Mr. Brudenell Carter, ophthalmic surgeon to the same institution. It will doubtless take many of the older members and fellows of the College by surprise to find that the Hunterian Professorship of Surgery, which has hitherto been occupied by a general surgeon, has this year been bestowed on a specialist. But it must be distinctly borne in mind that Mr. Carter is elected Professor of Surgery, with, of course, the tacit understanding that he will devote his lectures to some part of ophthalmology, although there is nothing to prevent him lecturing on any department of surgery that he may choose. We shall not now discuss whether it is well to make the chair of general Surgery and Pathology available for lectures on a special subject, important though it be; nor whether it would not have been preferable to have made a definite recognition of ophthalmology by instituting a separate course of lectures thereon, as has been done in the case of dermatology. Suffice it for the present, that the vacancy was duly advertised, and as Mr. Carter was the only applicant, he was nominated last month, and has been elected at a full meeting of the Council. Apart from this, there can be but one opinion of the worth of the newly-appointed professor. Mr. Carter, by his writings, discourses, and orations, has given us good grounds for expecting from him a course of carefully prepared lectures that will redound to the honour of the College, and will serve to advance the science and art of ophthalmology.

Other important business was conducted at the same meeting of the Council. A report was received from the Court of Examiners giving the number of candidates passed and rejected for the Membership during the year 1874–75; and a report, which we shall refer to at an early date, was presented by the President respecting the affairs of the College.

Sir James Paget succeeded Mr. Le Gros Clark as President, and Mr. Prescott Hewett and Mr. Birkett were made Vice-Presidents by rotation. Drs. Peacock and Wilks were again elected Examiners in Medicine; Messrs. T. A. Rogers and Barrett were elected Examiners in Dental Surgery; and Mr. Quain was re-elected the College representative to the Medical Council.

Medical News.

APOTHECARIES' HALL. — The following gentlemen passed their examination in the Science and Practice of Medicine and received certificates to practise on July 1st:—

Collins, Henry Abdy, Bayswater.
O'Callaghan, Kenneth Macdonald, Blackrock, Co. Cork.
Rees, Alfred, Maesteg, Glamorganshire.
Saunders, Edward Argent, Haverfordwest, South Wales.

The following gentlemen passed the Primary Professional Examination on the same day:—

Jakins, Percy Septimus, St. Mary's Hospital.
Skerman, Sidney, King's College.

At the recent examination for the prizes in Botany given annually by the Society of Apothecaries to medical students, the successful candidates were:—

1st.—Neville Scott Whitney, University College. Gold Medal.
2nd.—William Rushton Parker, University College. Silver Medal and Book.

ROYAL NATIONAL LIFEBOAT INSTITUTION. — A meeting of this deserving institution was held a few days ago at its house in John-street, Adelphi. Various reports were read, all proving the great usefulness of the Society. Several substantial contributions were announced in the course of the proceedings.

Dr. Ainley, medical officer of health for the Halifax borough, believes he has discovered the origin of the enteric fever which prevails within a small radius of the Northowram township. After a thorough investigation, Dr. Ainley has satisfied himself that the disease was introduced into the district by means of the milk supplied by a dealer who had fever in his house.

The death-rate of Berlin has been gradually increasing for some time past. We now learn that there is a large amount of sickness in the city, including what is called European cholera. With the hot weather advancing, and knowing the filthy condition of the Spree, we shall not be surprised to find an epidemic prevailing in a short time.

Health of Ireland.—From the Registrar-General's report for the quarter ending 31st March we learn that the births registered during that period amounted to 36,444, and the deaths to 30,589, or a mortality of 23·1 per 1000, the high death-rate being mainly attributable to the harsh weather and the prevalence of scarlatina. Small-pox also existed to a considerable extent, and the registrar of Bella, near Castlebar, states that a very malignant type of the disease caused 36 deaths, inoculation being still carried on to a great extent in the district. The following are the deaths from the principal zymotic diseases during the three months:—Scarlatina caused 1107 deaths, fever 769, diarrhœa 450, whooping-cough 322, small-pox 239, measles 195, diphtheria 128. The mean temperature was 42·9°, and the rainfall measured 6·816 inches.

Sanitary and Educational Exhibition.—An exhibition of sanitary, educational, and domestic appliances will be held from the 6th of October to the 16th, in the Corn Exchange, adjoining the Pavilion, Brighton, in connexion with the Social Science Congress to be held contemporaneously in that town. The object of the exhibition is to bring under the notice of the public generally, and particularly those who are interested in social, sanitary, educational, and economical questions, the latest scientific appliances for improving the public health, promoting education, and advancing social economy. These will be classified under the following heads:—1. Warming, ventilation, and lighting. 2. Domestic appliances and apparatus. 3. Sanitary architecture and appliances. 4. Sanitary engineering and methods for disinfecting. 5. Food and clothing. 6. School furniture and school apparatus.

Bequests, &c., to Medical Charities.—St. Mary's Hospital, Paddington, has received an additional £100 from Mr. Charles Baring Young, and an additional 50 guineas from the Clothworkers' Company. The Worcester Infirmary has become entitled to £500 under the will of Mrs. Jane Barton. The York County Lunatic Asylum has become entitled to £200 under the will of Mr. Green Simpson.

Medical Appointments.

Browne, T. H., L.K.Q.C.P.I., L.M., L.R.C.S.I., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Frankford Dispensary District of the Parsonstown Union, King's County, vice Ridley, resigned.

Buckley, Mr. T. W., has been appointed Dispenser and Assistant to the House-Surgeon at the Staffordshire General Infirmary, Stafford.

Callanan, Dr. M., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Kilbrittain Dispensary District of the Bandon Union, Co. Cork, vice Crowley, resigned.

Cogan, P. E., M.D., C.M., has been reappointed Medical Officer of Health for the Allerton Urban Sanitary District, Yorkshire, his term of office having expired on the 1st of May.

Davies, J., M.R.C.S.E., has been appointed Medical Officer to the Western Dispensary, Bath, vice Brabazon, resigned.

Davies, W. H., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer for the Mynyddislwyn District of the Newport Union, Monmouthshire, vice W. J. Davies, F.R.C.S.E., resigned.

Duncan, Dr. G., has been appointed Medical Officer and Public Vaccinator for the Parishes of Knockbain and Killearnan, vice Smith, resigned.

Duncanson, J. J. K., M.D., C.M., F.R.C.P.Ed., has been appointed Surgeon to the Dispensary for Diseases of the Ear, Cambridge-street, Lothian-road, Edinburgh.

Dunn, G., M.R.C S.E., has been appointed Medical Officer for No. 5 District of the Hertford Union, vice Smith, deceased: £60 for one year.

Edgeworth, H., F.R.C S.I., has been appointed Medical Officer for the Longford District of the Midland Great Western Railway of Ireland, vice Peter, deceased.

Eyeley, J. F., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer to the West Gloucestershire Friendly Society, to the Midland Railway, and to the Dursley Female Friendly Society.

Gray, F. A., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer of Health for the Ottery St. Mary Urban Sanitary District, vice Morrell, resigned: £20 per annum; acreage 9944; population 4107.

Hickson, A. T., M.B., L.R.C.S.I., has been appointed Assistant Medical Officer to the Lancashire Lunatic Asylum, Rainhill, vice De Denne, resigned.

Horne, J. F., L.S.A.L., has been appointed an Assistant Resident Medical Officer to the Leeds General Infirmary, vice Bower, resigned.

Huston, R. T., jun., L.R.C.S.I., L.K.Q.C.P.I., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Tynan Dispensary District of the Armagh Union, vice C. T. Huston, L.R.C.S.I., L.M., deceased.

Imlay, G. A., M.B., C.M., has been appointed Physicians' Assistant to the Bristol General Hospital, vice Thorneley, appointed Assistant House-Surgeon.

Kebbell, A., M.R.C.S.E., has been appointed Medical Officer for the No. 4 District of the York Union, vice Wright, resigned.

Kisby, W. J., L.F.P. & S. Glas., L.M., has been appointed Medical Officer and Public Vaccinator for the Ballyfarnon Dispensary District of the Boyle Union, Co. Roscommon, vice Nixon, resigned.

Lithgow, R. A. D., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Certifying Factory Surgeon for the Wisbech District, vice Maynard, resigned.

Lovett, H. A., M.R.C.S.E., L.M., has been appointed Second Assistant Medical Officer to the Worcester County and City Lunatic Asylum, Powick, vice Cooke, appointed Senior Assistant Medical Officer and Deputy Superintendent.

Mitchinson, C. C., M.R.C.S.E., has been appointed Surgeon to Lodge No. 7 of the Grand City Order of Odd Fellows, London.

Molony, J., L.R.C.S.I., L.K.Q.C.P.I., L.M., has been appointed Medical Attendant to the Royal Irish Constabulary, Drumahair, Co. Leitrim, vice Palmer.

Moore, A., L.R.C.S.I., L.K.Q.C.P.I., L.M., has been appointed Medical Attendant to the Royal Irish Constabulary, Collooney, Ballicodare and Ballintogher, vice Armstrong, deceased.

Pearson, G., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer to the Brass Station of the African Association of Liverpool, vice Stanmore, who retires on account of ill-health.

Thornley, J. G., M.D., L.R.C.S.Ed., has been appointed Assistant Medical Officer to the Leicestershire and Rutlandshire Lunatic Asylum, Leicester, vice Dixon, resigned.

Wacher, F., M.R.C.S.E., has been appointed a Surgeon to the Kent and Canterbury Hospital, vice Denne, deceased.

Watson, Mr. E. J., has been appointed Out-door Assistant to the Friendly Societies' Medical Institute, Northampton, vice Munro, appointed Medical Officer to the Bradford Medical Aid Association.

Welsh, F. F., F.R.C.S.E., has been appointed Medical Officer for No. 5 District of the Saffron Walden Union, Essex, vice Balding, resigned.

Wybrants, R. B., L.K.Q.C.P.I., L.M., M.R.C.S E., has been appointed Medical Officer and Public Vaccinator for the Wincanton East District and the Workhouse of the Wincanton Union, vice Cardell, deceased.

Wynne, W., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed House-Surgeon to the Bridgnorth Infirmary and Dispensary, vice Davison.

Births, Marriages, and Deaths.

BIRTHS.

Churchill.—On the 1st inst., at Sumner-place, South Kensington, the wife of Frederick Churchill, M.D., of a daughter.

Cooper.—On the 30th ult., at Leytonstone, the wife of Frank W. Cooper, L.R.C.S.Ed., of a daughter.

Fraser.—On the 30th ult., at Greenlaw-park, Mid-Lothianshire, the wife of H. M. Fraser, M.D., Deputy Surgeon-General, of a daughter.

Gordon.—On the 29th ult., at Herbert Hospital, Shooter's-hill, the wife of H. G. Gordon, M.D., Deputy Inspector-General, of a son.

Jones.—On the 27th and 28th ult., at Weston-super-Mare, the wife of E. S. Jones, L.R.C.P.Ed., of twin daughters.

Kerr.—On the 2nd inst., at Grove-road, Regent's-park, the wife of N. S. Kerr, M.D., of a daughter.

Mackay.—On the 30th ult., at Palmfield House, Crook, *viâ* Darlington, the wife of Alex. Mackay, M.D., of a son.

MARRIAGES.

Adams—Harvey.—On the 6th inst., at H.B. Majesty's Legation, Brussels, J. O. Adams, F.R.C.S., to Anne, daughter of the late Francis Harvey, Esq., of Thringstone, near Ashby-de-la-Zouch, Leicestershire.

Newington—Barnes.—On the 1st inst., at St. George, Hanover-square, Alex. Samuel Lysaght Newington, M.B., to Mary Gertrude Fancourt, daughter of Robert Barnes, M.D.

DEATHS.

Body.—On the 18th ult., at Crediton, Josiah Body, L.R.C.P.Ed., aged 65.

Crichton.—On the 5th inst., at Mortlake, Surrey, Alexander Crichton, L.R.C.P.Ed., L.R.C.S.Ed., aged 31.

Farr.—On the 25th ult., at Truro, G. E. Farr, M.R.C.S.E., aged 41.

Gouthwaite.—On the 4th inst., at Tranmere, Thos. Gouthwaite, M.D., aged 73.

Griffith.—On the 14th ult., at Westbury, Chas. Griffith, Surgeon, aged 70.

Johnson.—On the 30th ult., at Taunton, F. P. Johnson, M.B., aged 32.

Langworthy.—On the 17th ult., at Ermington, Devon, Southmead Langworthy, M.R.C.S.E., aged 46.

Rumbold.—On the 26th ult., at New North-road, T. Rumbold, M.R.C.S.E., aged 58.

Wardroper.—On the 26th ult., at Epsom, Wm. Wardroper, M.R.C.S.E., aged 71.

Willett.—On the 10th ult., at St. Chad, Shrewsbury, John Willett, M.D., aged 35.

Wolfe.—On the 29th ult., at Bonn-on-the-Rhine, H. Wolfe, M.D., aged 81.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*]

Notes, Short Comments, and Answers to Correspondents.

Poisoning by Goats' Milk.

Throughout the month of June the inhabitants of the Rione Borgo in Rome suffered from quite an epidemic of gastro-intestinal irritation; in other words, from vomiting, pains of the epigastrium and bowels, with diarrhœa, thirst, shortness of breath, pallor, small and frequent pulse, and lowering of temperature. The symptoms were traced to the consumption of goats' milk, and were more or less severe according to the quantity of milk consumed. In some cases a healthy reaction set in within the twenty-four hours; others took four or five days to get round. Veterinary surgeons examined the goats from which the milk was taken; but nothing was found wrong with them. Professor Ratti, of the Sapienza, then subjected to chemical analysis the vomitings of the sufferers and the milk of the goats, and, in the first instance, found no trace of metallic poisoning. He next proceeded to the goats' pasturage, and found, among the herbage on which they browsed, four species of plants, all more or less poisonous—Conium maculatum, Clematis vitalbula, Colchicum autumnale, and Plumbago Europea. Every one of these bore marks of having been nibbled by the goats. Fresh experiments were then made on the vomitings and the milk, and Professor Ratti detected in both a solid matter of yellow colour, which yielded the chemical reactions of colchicina. The Colchicum autumnale had passed in the form of its alkaloid from the plant to the milk, and the drastic and other symptoms from which the consumers of the milk had suffered were at once explained. An attempt was made at the meeting of the Roman Academy of Medicine to supplement Professor Ratti's induction, by showing that Momordica elaterium was among the pasturage of the goats, and that its passage into the milk might account for the symptoms in the consumers, if not wholly, at least in part. But it was shown that the goats instinctively avoid this plant, and Professor Ratti's impeachment of the Colchicum autumnale remained, at the end of an animated discussion, untouched.

Dr. Fredk. Robinson.—We are sorry the communication cannot be inserted.

Solution of Lead as a Dressing.

To the Editor of The Lancet.

Sir,—In relation to the use of acetate of lead, I can fully confirm the favourable opinion expressed by Mr. Hutchinson. The prescription I have used, however, is different—viz., acetate of lead, ten to twenty grains; limewater, half an ounce; water, half an ounce. This gives a ready way of forming a solution of diacetate of lead, as the limewater takes up any free acid; while, so far as I can judge, the small proportion of precipitated lead, along with the acetate of lime probably formed, are useful adjuncts in promoting the healing and antiseptic properties of the lead lotion. At all events, this is the mixture I have used for about eight years to ulcers, wounds, and burns, without the remotest evidence of lead-poisoning, however extensive the injury treated. With the exception of boracic acid, which I have never tried, it seems to me to possess considerable advantage over every other antiseptic dressing. Thus with carbolic acid there is often disappointment at the amount of time taken to complete the cure, the acid seeming sometimes to even retard healing by, as I believe, checking granulation; while with this lotion a burn, severe in depth and extent, not only heals rapidly, but with an early remission of pain, and the resulting cicatrix so thin as to be almost transparent—in this respect rivaling the result claimed for boracic acid by Prof. Lister. Further, it has the great advantage of obviating the necessity for transplanting, because, whether at the edges or in the centre of a sore, wherever the lead is fairly deposited and a coating obtained, healing at once goes on beneath. It is consequently of paramount importance to produce the coating, and to do so I believe it will generally be found to be the best plan to keep, as far as possible, the lint or other dressing from coming in contact with the sore. Thus I sometimes take a syringe, and by it apply the lotion to the injured surface till a complete white coating is obtained; a ring made up of soft cloth to about half an inch in thickness, and of sufficient diameter to rest only upon sound skin, is fixed on, and over this a piece of lint, so that there is protection without contact. By repeating the irrigation every two or three hours, suppuration is almost entirely prevented, while the sore will be found healing from points in the centre as well as at the circumference. As the lead forms a firm crust, albuminate or fibrinate, with the discharge it is necessary in large sores that this crust should be carefully removed, lest it interfere with the healing process.

In the treatment of ulcers, whether of the healthy, weak, or indolent variety, the lead lotion is highly serviceable; whilst in the inflamed and especially in the irritable ulcer, where pain is usually so intense and healing difficult to obtain, relief is rapidly afforded; the sore becomes covered and protected by a crust, which sometimes rises considerably above the level of the skin; surrounding inflammation speedily subsides, and cure is often very quickly effected. In these cases, after applying lint soaked in the lotion to the whole inflamed surface till all inflammatory redness is gone, the dressing should then be made as nearly as possible the size and shape of the sore. It should be moistened every hour or two hours, be allowed to dry in the interval, be changed twice daily, and be thoroughly soaked with the lotion before removal. Of course, as with every other application, peculiarities in the case will call for modifications in management; yet, so far as my acquaintance with the remedy goes, the points mainly to be attended to are, a coating to the sore, and care that it be not prematurely rubbed off.

In conclusion, while discharge is not entirely prevented, it can, with very moderate attention, be kept so changed as to be free from putrefactive odour.

I remain, Sir, yours truly,
James Lawrie, M.D.,
Physician to the Dispensary of the Glasgow Royal Infirmary.
Glasgow, June, 1875.

Want of Mortuaries.

Dr. Bridges, Local Government Board Inspector, in reporting on the condition of the Shoreditch Workhouse Infirmary, complains of what must be considered a disgraceful state of affairs in the following words:—

> "Another serious nuisance pointed out to me was the habit of bringing in dead bodies and depositing them in the mortuary of the infirmary, owing to there being no mortuary belonging to the vestry. At the time of my visit there were three bodies, all 'found drowned' in the Regent's Canal, and two of them in a very advanced state of decomposition. The entrance to this deadhouse communicates directly with the corridor leading to the infirmary. I can conceive nothing so utterly at variance with sound sanitation as that decomposing bodies should thus be brought into proximity with the wards of a hospital. It is the business of the vestry to provide a mortuary. The workhouse hospital is not the proper place for it."

We are glad to find that the Shoreditch guardians have since called upon the vestry to provide a mortuary, and signified to them that they will after the expiration of a certain date refuse to receive at the workhouse dead bodies as heretofore. We fear there are many other workhouses in London where the practice censured by Dr. Bridges prevails.

Miners' Nystagmus.

To the Editor of The Lancet.

Sir,—While admitting the accuracy of Dr. Taylor's description of the form of nystagmus met with among miners, I confess I was not a little surprised at finding it spoken of as a "new disease." This feeling will, no doubt, be shared by most surgeons who are engaged in ophthalmic practice in colliery districts.

It is now some years since, while attending the Leeds Infirmary, that my attention was drawn to the frequency of this affection among colliers, and it was then generally called "miners' nystagmus," a name one has become accustomed to apply to it. Although it may not be referred to in our text-books, and nystagmus only very briefly dealt with, yet ophthalmic literature is not quite devoid of some reference to miners' nystagmus. I would refer Dr. Taylor to the *Annales d'Oculistique* for November and December, 1872 (page 241), for a summary of an article by Dr. Paul Schroeter (from the *Klinische Monatsblätter für Augenheilkunde* for 1871), on "Nystagmus chez des Mineurs." Two cases are reported, both patients following the employment of miners. In each case the eyes themselves did not present the least alteration; vision, accommodation, and the associated movements of the organs were normal. The oscillation increased towards evening. In the first of these cases the author had recourse without success to "un courant d'induction, à l'application d'un vesicatoire, etc. Mais l'administration de la noix vomique à faible dose parvint a vaincre ce mal si rebelle." He considers the affection a simple neurosis, depending perhaps on a slow intoxication by the deleterious gas disengaged in coal pits.

Again, in the *British Medical Journal*, January 3rd of last year, there is also a communication by my friend Mr. Oglesby, of Leeds, "On a Peculiar form of Nystagmus," where he says, "A fact worthy of special note is that all the patients as yet examined are by occupation colliers," and enters into a full description of this affection.

Four cases of miners' nystagmus have come under my observation during the last few months, and from these, and other cases previously noticed, it seems to me that this disease occurs chiefly, if not entirely, in those colliers who are obliged to do their work in the pit whilst lying on one of their sides. I have also noticed that the oscillatory movements of the eyes have not only been to and fro horizontally, but also somewhat rotatory round their antero-posterior axes. Every medicament has seemed to me for the most part ineffectual, though in one case bromide of potassium appeared to lessen the oscillations.

I quite agree with Dr. Taylor that a discontinuance of occupation in the pit is of all-importance in the treatment of this disease, and it will be especially serviceable in recent cases, like those mentioned by him; but if of long standing, as one my attention was called to lately of more than twenty years' duration, little improvement could be expected from such change.

My friend and colleague, Mr. Gillott, informs me he has been familiar with nystagmus among colliers for many years. He also says he has performed tenotomy in two cases with perfect success. First in 1867, and again in 1873, and both of these patients have since followed their employment in the pit without recurrence of the disorder.

I am, Sir, yours &c.,
Simeon Snell, L.R.C.P. Lond, &c.,
Surgeon to the Sheffield Eye Dispensary.

Urethrotomy or Lithotomy in Aged and Debilitated Persons.

To the Editor of The Lancet.

Sir,—In your issue of May 30th, 1874, appeared a letter signed G. Turnley, professing to be a statement of facts in connexion with the operation of urethrotomy and dilatation of the prostate as performed by myself. That it is so I most strongly demur, and, in proof thereof, quote the following from the ward register of the General Hospital, the same being public property, and, although always open to inspection, has never up to the present moment had its accuracy challenged.

"C. H."—Dr. Turnley says "I made a preparation of this man's bladder. The prostate was so extensively lacerated that the little finger could be laid in the rent."

The public register kept in the hospital, and the case fully entered immediately after the post-mortem had been made, records: "*The annular arrangement of the prostate was intact, the parts through which the stone had passed being free from injury.*"

It was not until my son arrived from England that Mr. Turnley's letter was pointed out to me, it having escaped my notice. I at once applied to see the preparation. Judge of my astonishment when I was informed "*that it had disappeared, and was nowhere to be found.*"

I am, Sir, yours truly,
William L. Crowther.
Hobart Town, May 8th, 1875.

A GOOD MOVE.

A NUMBER of gentlemen in Glasgow have banded themselves together for the purpose of defacing the announcements of quack doctors, which are frequently exhibited in large numbers on the walls and hoardings of the city and suburbs. They have employed a man to go round and cover over all such bills with "lamp black," and it is said that in doing so he will have the protection of the police. The practice initiated in Glasgow may well be copied in all our large towns. The offensive bills and advertisements which the quacks of London are permitted to affix on dead walls and other places, and which constitute such an eyesore to decent passers-by, would take a small army of men with lamp black to obliterate.

PREPARATION OF SECTIONS OF BRAIN-SUBSTANCE.

To the Editor of THE LANCET.

SIR,—Having been engaged for some time past in the histological laboratory of University College in examining the structure of the brain, I venture to send you the following description of a process of preparing sections of that organ, which, after trial of numerous modes, I have found to yield most satisfactory results, and which I believe is in many respects entirely new. The process is as follows.

The brain is to be operated on just as it is obtained from the subject, without the employment of any hardening or preserving reagent. Sections or slices are to be made of the part the operator wishes to examine by means of a large amputating knife, kept constantly wet with spirit. Sections should be made as thin as possible; but those of one-eighth or even one-quarter of an inch in thickness will answer the purpose. Having obtained a sufficient number of these sections, they are to be dyed. The dye I use, and which I have selected after the trial of very many reagents, is a half per cent. solution of aniline black (this can be obtained from Hopkin and Williams, Hatton-garden). It is of a dark purplish-blue colour, and when used of the above strength the solution has the appearance of ink. The sections should remain in the dye for from six to twelve hours, or until they have acquired a very deep colour. The dye is then to be poured off, and the sections washed by the addition of fresh water, when they should be floated on to the slides, and placed in position. All excess of water should be wiped from the slides, which are now to be put in a dry place for a few days, until the preparation has undergone complete desiccation. Should the sections be very thick, gentle warmth may be necessary, in order that they may dry before putrefaction occurs. The portions of brain will now be found firmly adherent to the glass, and of such a consistence that it can be easily pared down with a razor or sharp scalpel. I have, however, contrived an instrument which is much more efficient. It consists of an ordinary two-inch rebat plane, such as carpenters use, but which I employ the reverse way, or with the blade uppermost. On each side of the plane are fixed adjustable guides, which can be raised to various heights above the cutting edge of the plane. The slide with the preparation downwards is passed over the knife, and the shaving is gradually regulated by the set screws until the section is sufficiently reduced in thickness. The preparation may then be cleared with varnish, and examined and mounted if found satisfactory. The method is particularly adapted to display nerve-cells and their processes.

I remain, Sir, yours &c.,

University College, June 21st, 1875. H. R. O. SANKEY.

Register.—Has not our correspondent been incorrectly informed? We have always understood that army medical officers are required to place their names on the Medical Register. As regards the holders of appointments in the Indian and Colonial services, however, we cannot be so sure.

CASE OF RAPID HEALING OF ABSCESS IN THE GROIN.

To the Editor of THE LANCET.

SIR,—The following case may be worth recording, as an example of the way in which nature will sometimes take a case out of our hands, and, in utter defiance of the all-pervading "germs" about which we hear so much, will set to work in her own way, and heal up a considerable abscess cavity as if by magic.

Mrs. ——, wife of a well-to-do tradesman in this town, came under my charge six weeks after confinement, suffering from phlebitis of right saphena vein, which presented the usual hard, painful cord in the groin, and accompanied with a good deal of fever, loss of sleep and appetite, wasting, and night-sweats—in short, the patient was run down pretty low, the case being undoubtedly one of phlegmasia dolens, but without the œdema so characteristic of that disease in general. The treatment consisted in keeping the part poulticed, and supporting the strength with liquid nourishment, little and often, Dover's powder at night, &c. After a fortnight, fluctuation became apparent in the groin. The abscess was opened in the ordinary manner, and three ounces of healthy-looking pus let out. Fully expecting a tedious suppuration and a slow healing of the cavity, I laid in a stock of tenax and a large bottle of carbolic lotion in preparation therefor. The cavity, however, got only one syringing with the lotion, as I was called away a distance of forty-five miles (which in this part of the world, and in midwinter, means an absence of not less than three days), and on my return Dr. Simms, who had kindly undertaken to see the case for me, informed me that he had found, on visiting the case the day after I left town, the wound all but closed, and no discharge, nor, in fact, anything calling for interference; and on my visiting the patient four days after the opening had been made I found the wound quite healed, the cavity obliterated, and no trace of pain or tenderness remaining; in short, it was completely well, healed by first intention, one might almost say. The patient after this rapidly picked up flesh and strength, and is now well.

Now, if I had been a disciple of Prof. Lister's, and a believer in his germ theory, and had treated this case accordingly with a like result, not all the Colleges of Surgeons combined would ever have convinced me that the said result was not owing to my antiseptic dressings and precautions. I am taking it for granted that a simple and single washing out with weak carbolic lotion, with a pad of oakum and a bandage, will not be called antiseptic dressing—at least not by those who go in for opening abscesses under a cloud of spray, and all the subsequent complicated dressings, gauzes, boracic lint, &c., which are described as indispensable to that form of treatment.

I am, Sir, your obedient servant,

St. John's, N.F., April 27th, 1875. THOS. HOWLEY, L.R.C.S.I., &c.

FORTY YEARS' SERVICE AS PAROCHIAL MEDICAL OFFICER.

WE are glad to learn that the Dover Board of Guardians have unanimously voted a retiring pension of £130 a year to Mr. John Walter on his retirement from the office of Surgeon to the Dover Union. Mr. Walter has spent forty years of his life in the Poor-law medical service, and, while congratulating him on his well-merited pension, we cannot help expressing our regret that the service is so badly paid as compared with other public departments.

ENTERIC FEVER.

To the Editor of THE LANCET.

SIR,—In the address of Sir William Jenner delivered before the Clinical Society on the "Etiology of Enteric Fever," I noticed with interest that he regards the experience of private practitioners who have to do with isolated cases of the disease as being of value in deciding the vexed question of the nature of its origin. In accordance with this suggestion, I venture to offer you the history of two outbreaks of enteric fever within my own practice—one I think showing as clearly as possible the generation of the disease from putrid sewage; the other, its communicability under favouring circumstances.

The first mentioned of these occurred in a house most healthily situated on one of the spurs running down toward Lyttelton harbour, at least 250 feet above the sea level; the house was only a few years old, and no case of fever or in fact of disease of any kind had occurred in it previously. Only one house was situated higher on the spur, the drainage from which led quite away from it, and the occupants of which had never suffered from fever in any form. As is usual with houses built in such a position, there was a considerable excavation into the hill at the back, round which was a catch-water drain on the surface, running along the back and by the side of the house, intended to carry off storm water, but which had been for a long time used as a channel for getting rid of dish washings and house slops, and which at the time spoken of had become foul for the want of sufficient fall. On the 12th April, 1871, the weather at the time being very hot, Mr. K——, the occupant of the house, with some of his children, set to work to clean out and deepen this drain. They suffered considerably from the stench, which permeated the house, and caused nausea to those within as well as to themselves. On the 21st I was called in to visit one of the younger children, who had unmistakable symptoms of typhoid, and within three days the whole family, including Mrs. K——, who had been confined on the 19th, were all, seven in number, down with the same disease, which in each case presented the true signs of typhoid fever—diarrhœa, deafness, delirium, &c. All recovered, and it is worthy of note that at the time there was not another case of typhoid, as far as I was aware, existing in the town, nor did it spread among those who were in attendance upon the family.

I cannot but think that this was a case of generation of the disease *de novo* from the putrid sewage disturbed in the alteration of the drain around the house, as I cannot see the possibility of any typhoid excreta having been present.

The other instance occurred among the families of the miners employed in making the Moorhouse Tunnel, which connects the port with the Canterbury Plains. It started with a young girl, who had left a family with whom she had been servant, in Christchurch. She came home to her friends, who were living in a small cottage in the Heathcote Valley, where a large number of the miners dwelt, complaining only of lassitude, want of sleep, and loss of appetite, and but for the fact that two deaths from fever had occurred in the house she had left I should scarcely have considered her case as one of the kind. Within a few days two of her sisters living in the house, and the children of one of them, were suffering with true typhoid; the mother, who officiated as a midwife, had conveyed the disease to a woman in childbed, who eventually died from it; and several of this patient's friends, who, in spite of my remonstrances, would crowd the little cabin in which she lived, sickened with the same fever, and these in turn communicated it to their husbands; so that within three weeks of the advent of the first patient I had *twenty-two* cases of typhoid, all traceable to the one source. These were entirely among the Cornish families, who had but recently arrived in the colony, and whose huts were for the most part damp and devoid of comfort, and who had not yet accustomed themselves to the more generous diet which the older colonists indulged in, living on a very small allowance of animal food, supplemented largely by indigestible material in the shape of "pasties" &c.; while the old Victorian diggers, who formed the larger body of the workmen, and who lived in rough plenty, had not a single case among them, although in some instances living under the same roof with fever patients.

I am afraid I am trespassing too much on your space with this communication, but think that it may be of some interest to those who are engaged in the investigation of the causes and nature of enteric fever—a matter of great moment to us in New Zealand at the present time, as there is scarcely a town throughout the colony that is not suffering severely from its ravages. Here they have not been confined to class or locality, many of the cases occurring in the most healthy and well-drained positions, and among the scrupulously cleanly; while in some places, where the reverse of this has obtained, the fever has been almost or entirely absent.

I am, Sir, yours faithfully,

JOHN T. ROUSE, L.M. Lond.,
Assistant Provincial Medical Officer, Littelton, N.Z.

Lyttelton, Canterbury, New Zealand, March 5th, 1875.

THE INTERNAL ADMINISTRATION OF PICROTOXIN.

A CORRESPONDENT wishes to know in what doses the active principle of cocculus indicus is administered in epilepsy, as advocated recently by a French physician.

THE FAMILY OF THE LATE MR. THOMAS.

To the Editor of THE LANCET.

SIR,—Allow me to avail myself of this opportunity to thank you personally for your kind co-operation on behalf of the widow and family of the late R. Thomas, Esq., surgeon, of Etwall, Derbyshire, and also to convey the thanks of the widow and family to you and to the subscribers to the Fund. Would you kindly acknowledge £5 from "A Friend at Kurrachee," per the Secretary to the Church Missionary Society, resident at Bombay. It may give you pleasure to hear that the Fund from all sources now amounts to upwards of £170.

Yours truly,

Burton-on-Trent, July 5th, 1875. FREDK. WILKINS.

Private Friendship and Medical Certificates.

A correspondent very properly calls our attention to the conduct of the Great Britain Mutual Life Office in directing a series of questions to him, a medical man, as to the health and habits of a candidate for insurance. To expect such information from a medical man, except on the ordinary professional terms, is not reasonable. Possibly the Office may not be to blame, but the candidate.

Fatal Peritonitis, in which the Patient pursued his Avocations until within a few hours of Death.

To the Editor of The Lancet.

Sir,—I remember having once incurred the ridicule of an experienced medical friend by telling him that a patient whom I had pronounced to be the subject of acute peritoneal inflammation was sitting up in bed reading a newspaper. In that case the subsequent course of the disease and a post-mortem examination established the correctness of the diagnosis; and I refer here to the opinion of my friend only as an illustration of the error into which we may be led by trusting in practical medicine to the guidance of mere presumptive evidence.

The case which I am now about to relate is an example of severe peritoneal inflammation, ending in collapse and death, and yet in which the patient followed his usual avocations until within twenty-four hours of his decease, and in which a resolution to disguise the severity of his illness apparently sufficed to mask a disease, whose prominent diagnostic signs are excessive pain and tenderness.

D. S——, a Frenchman, aged about sixty, had lived for several years as butler in an English family. On Wednesday, the 23rd ult., I received a note from the lady in whose service he was, asking me to go and see him, as he was very ill. I went to the house soon after, and the patient, clad in his ordinary attire, presented himself to me immediately in the dining-room. The servants subsequently told me that he had put on his coat, and came upstairs to see me, with an unusual degree of briskness. He gabbled about himself, as only an excitable Frenchman can, and it was with difficulty I made out that he had been ailing for the space of a week. He spoke lightly of his complaint, and particularly wished me not to trouble his mistress in reference to it. It appeared that he had walked some distance in the morning, had taken something to drink in company with another servant at a public-house, and had waited on the family as usual at luncheon. About twelve o'clock on the same day he had taken two pills, and at four o'clock he was seized with severe abdominal pain, which obliged him to throw himself on the ground. This was the only history I could obtain. As there was no couch in the dining-room on which he could lie, I made the man go downstairs again to his bed in the pantry, in order to examine the abdomen. I observed that he descended the stairs rapidly, and without making the smallest complaint of pain. On exposing the abdomen, it appeared somewhat retracted; but there was absolutely no tenderness on pressure over the cæcum or elsewhere; there was no hernia, and he said the bowels had acted on the previous day. I next inquired into the composition of the pills he had taken, and was shown a box of them, labeled "Podophyllin pills," which he told me had been prescribed for him by a neighbouring chemist. I then ordered six drachms of castor oil, with ten minims of liquid extract of opium, to be taken immediately, and directed him to apply a hot linseed poultice. On my way home I called at the chemist's to ascertain the exact strength of the pills, and found that two of them contained rather more than half a grain of podophyllin, besides a certain quantity of colocynth. To the characteristic action of two such purgatives I not unnaturally attributed the pain that had come on about four hours after they had been swallowed, and I thus felt tolerably certain that the symptoms exhibited were in great part accounted for. The three female servants sat up with him during the night, and reported that he became worse about half-past four in the morning. However, I was not summoned again till half-past one in the afternoon, and when I arrived about two o'clock the man was in a state of collapse, and died at five o'clock, within twenty-four hours from the time I had first seen him. He talked volubly to the last, turned without complaint from side to side, and kept his legs and thighs constantly extended.

Dr. Green kindly assisted me in making the post-mortem examination. On opening the cavity of the abdomen, evidence of severe peritoneal inflammation was immediately perceptible. The coils of intestine were wreathed with lymph, the various tissues were injected with blood, and the abdomen contained some pints of effused fluid. Each viscus was examined in turn for evidence of ulceration; but the stomach, gall-bladder, and appendix vermiformis were found intact, as was also the intestine, which was divided and carefully inspected throughout its entire length. The mucous membrane lining the intestinal canal was in a state of catarrh, and somewhat thickened, probably from the long-continued use of purgative medicine, and the intestines were quite empty. There was no intussusception present, nor any twisting of the gut, and the kidneys were found to be healthy.

In our opinion the condition that presented itself had been brought about by over-purgation, and I have since learned that the unfortunate deceased had taken as many as six of the above pills at a time.

I imagine the case may possess some interest in a medico-legal point of view; but it is also interesting clinically, as it is remarkable to find such a degree of idiopathic peritonitis co-existing with so few of the well-known and characteristic symptoms of that affection.

I remain, Sir, yours truly,
Sussex-gardens, Hyde-park, July, 1875. T. Fitzpatrick.

Mr. F. T. Williams, (Stoke Newington.)—We never recommend a particular physician or surgeon.

Pruritus Ani.

To the Editor of The Lancet.

Sir,—Some weeks since I saw a letter in your journal, recommending the use of "Wright's liquor carbonis detergens," in the proportion of one of the liquor to three of water, for pruritus ani. Having for years suffered from this disease, I followed the recommendation, and with entire success, and I think it due to the recommender of the remedy, to its inventor, and to sufferers like myself, to bring my experience to your notice.

Your obedient servant,
July, 1875. Civilis.

P.S.—I enclose my card that you may not think I am acting from interested motives.

A would-be Keeper of the Law.—A case of typhus fever is certainly a medical case. But if the passing of a catheter was required in it, that would be a surgical duty. Bleeding for pneumonia would not so clearly entitle the phlebotomist to recover if he had nothing but a surgical qualification. There are no legal decisions defining the line of demarcation between surgical and medical cases, but generally it is not indistinct.

The Apothecaries' Society.

To the Editor of The Lancet.

Sir,—I am no longer a young member of the Apothecaries' Society, and as I have in my turn incurred the expense of the stewardship of the first dinner imposed upon all members, and paid the fine of £30 in lieu of incurring last year the like cost of that of the herbarising dinner, I trust that interested motives cannot be attributed to me in now offering a few additional words from my humble pen to those which have already appeared in your able journal.

For many years I have, on principle, declined to attend any of these dinners, and my principle is this: When I discharged my proportion (as one of the stewards) of the first dinner, it was only then first known to me on whose shoulders the expenses of these dinners were levied. Hence I then felt, as I still feel, that I might on the former similar occasions have been entertained at the cost of some who could ill afford it. Such, indeed, is the probability. So I deem it just and honourable to stay away. If this view were generally adopted and acted on, these dinners would soon collapse. In paying the fine of £30, as before stated, and requesting my name to be removed from the list of stewards, I further carried out this principle.

You will perhaps kindly excuse my adding that I knew nothing of my having been promoted to the office of steward last year until I received a formal invitation to the dinner for myself and three other members, nominated as stewards. To such a high mode of compliment I am certainly not accustomed; nor am I in the habit of receiving such a peremptory letter as that which I got from the clerk in reply to my own, declining to serve, and asking my name to be taken off the list. It was, in its entirety, as follows: "You must serve, *or* pay a fine of £30."

It has been stated to me officially that no member is ever called upon to serve as steward, and thus bear the charge of nearer £80 than £60, who is not well able to afford it. But, in answer to this, let me ask, how can the authorities of the Society, or how can you and I, possibly ascertain the actual means or pecuniary position of the members? Have they access to our banking pass-books?

I am not ashamed of the name I bear, and see no reason to withhold it.

I remain, Sir, your faithful and obedient servant,
Whetstone, July 6th, 1875. G. Bury.

To the Editor of The Lancet.

Sir,—I trust that you will not allow your able advocacy of the abolition of the now effete and useless apothecaries' dinners to be diverted from the main question (which has not been even touched upon by your correspondent, "Another Member")—viz., the compulsory mulcting to the extent of £60 of those members who find it no slight hardship to provide this sum for dinners, which they neither approve nor attend. If "Another Member" desires "the opportunity of social companionship and good fellowship," let him take the initiative in a plan similar to that adopted by the Fellows of the College of Surgeons, and invite members of congenial views to a dinner or a series of dinners, when each one pays for his own ticket. I feel sure that the eminent provincial member who has taken up the cudgels in the cause of his fellow-dissentients will receive not only their warmest thanks, but their earnest and practical encouragement.

I am, Sir, your obedient servant,
July 5th, 1875. A Member of the Second Class.

An Intending Candidate will, doubtless, obtain the information he desires by applying to the Secretary at the College.

Nemo.—We are not acquainted with a work of the kind.

German Medical Literature.

To the Editor of The Lancet.

Sir,—"Fatherland" may find a work entitled "Lateinisch-Deutsches Wörterbuch für Medicin und Naturwissenschaften, bearbeitet von Dr. Ernst Gabler (published at the Verlag von Hermann Peters in 1857), useful to him. This work was got in Berlin to supply the want felt by "Fatherland" until the language *medically* had been mastered.

I remain, Sir, yours truly,
July 3rd, 1875. Farquharson.

To the Editor of The Lancet.

Sir,—"Fatherland" would, I think, find the assistance he requires in the second part of Dr. Shirley Palmer's "Pentaglot Dictionary of Medical and Scientific Terms." The copy in my possession was published by Longman in 1845, and I am not aware whether or no the book is still in print; but the medical booksellers would, of course, be able to inform him.

Yours faithfully,
July 5th, 1875. Germanicus.

Registration.

To the Editor of The Lancet.

Sir,—As everyone is desirous of knowing to a certain extent what purpose money is put to that he expends, could you inform me what becomes of the £5 fee paid for registration? and also if a qualified, non-registered practitioner lays himself open to a penalty by giving certificates of cause of death?

Your obedient servant,
July, 1875. Enquirens.

⁎⁎⁎ The £5 fee goes to defray the expenses of the General Medical Council, by which body the Medical Act is administered. A non-registered, but qualified, practitioner who gives a certificate of death does not expose himself to the risk of penalty. He must not, of course, represent himself as registered. Registrars are often too ready to take certificates even from unqualified practitioners. They may mark such deaths as uncertified; but they register them, nevertheless, on the strength of the certificates. Registrars are not supplied with the Medical Register, and are not guided by it.—Ed. L.

L.R.C.P. Lond.

A correspondent writes to us to say that he has lately had over a hundred cases in various provincial County Courts, and in every case he obtained a verdict with full costs on the strength of the L.R.C.P. Lond. The decision of the County Court Judges proves the value of the qualification.

Purpura treated with Arseniate of Iron.

To the Editor of The Lancet.

Sir,—On the 30th of April a girl, aged seven years, was brought to me, complaining of headache, languor, and loss of appetite. On examination, I observed numerous purple and red spots, slightly elevated, as if pinched by a pair of small-pointed forceps, situated on the trunk, legs, arms, lips, and fauces. The mother informed me that frequently of late the child had vomited dark-coloured blood, that also blood had come from her nostrils, and had been passed at stool. Before I saw her she had been treated with saline purgatives without any beneficial effect, and was in an extremely weak state. Contrary to the treatment of Drs. Parry, of Bath, and Harty, of Dublin, I prescribed a tonic in the form of arseniate of iron, at the same time beef-tea and other nutritious diet. In the course of five days the marks began to fade, the sores at the angles of the mouth healed up, no more blood was either vomited or passed at stool, and in a fortnight no traces of the disease were seen. The appetite returned, accompanied by strength, and now she is as strong as, if not stronger than, she was before her illness.

I remain, Sir, yours &c.,

Pathhead, Scotland, July, 1874. J. Lindsay Porteous.

Errata.—In the letter of "Chirurgeon" on the Fellowship of the College of Surgeons, published in our last, page 41, two inaccuracies occur which it may be well to correct. Near the end of the second paragraph, for "three months' dissection," read "*eight* months' dissection"; and in the last line but one of the third paragraph, for "for," read *of*.

Communications not noticed in the current number will receive attention in our issue of the ensuing week.

Communications, Letters, &c., have been received from — Dr. Barnes, London; Dr. Wilson Fox, London; Mr. A. Smee, London; Mr. Ady, Wolverhampton; Mr. S. Snell, Sheffield; Mr. R. Lectures

ON SOME

NERVOUS DISORDERS THAT RESULT FROM OVERWORK AND MENTAL ANXIETY.

BY GEORGE JOHNSON, M.D., F.R.S.,
PROFESSOR OF MEDICINE IN KING'S COLLEGE; PHYSICIAN TO KING'S COLLEGE HOSPITAL.

LECTURE I.

GENTLEMEN,—I wish to direct your attention to a very numerous and interesting class of cases, in which a great variety of so-called nervous symptoms are traceable to the influence of overwork, anxiety, or mental shock. For the last quarter of a century I have taken an especial interest in cases of this kind, and so long ago as the year 1853, in a course of lectures which I delivered at the Royal College of Physicians, I described their general features, and gave a considerable number of examples illustrative of their etiology, their symptoms, and their successful treatment by a cautious temporary use of opium at bedtime. Up to that time my experience of these cases had been gained chiefly as a dispensary physician and in the out-patient rooms of the hospital. Since then I have met with them in all classes of society, and I know of few forms of disease in which a treatment based upon the recognition of the true nature and origin of the symptoms is, in a large proportion of cases, attended with more entirely satisfactory results. My treatment of these cases is essentially the same now as it was then, but the substitution of chloral for opium as a temporary soporific is a great practical gain. I say emphatically, as a "temporary soporific"; for I shall hereafter show you that I resort to the chloral only to tide over a temporary difficulty. Few drug-evils can be greater than that involved in the habitual employment of soporifics of any kind.

I shall endeavour to convey to you an accurate idea of the diseases in which I now desire to excite your interest, partly by a brief history of a few typical cases, and partly by a general description of their leading and characteristic features. In order to give greater variety and completeness to my illustration of these maladies I shall select some cases from those which I observed in my hospital practice many years ago, and others from the more recent records of private practice.

I beg it to be understood that in using the terms "mind" and "mental," as I shall frequently have to do in the course of these lectures, I mean by these expressions no more than is implied in their use by scientific psychologists. We know nothing of mind as a separate entity—apart, that is, from cerebral organisation and function. Mind is an abstract conception, like heat or motion, and it is conveniently used to designate a set of complex psychological energies. It comprehends volition, reason, affection, &c.—phenomena which are inseparably associated, so far as we know, with a material organisation. As physiologists, in our study of mental phenomena we make no reference to theological doctrines or metaphysical theories. We have no sympathy either with those who charge physiologists with materialism or with those who contemptuously speak of theologians as superstitious. With this preliminary explanation I will give you my first illustrative case.

CASE 1.—Mrs. L——, aged sixty-five, the wife of a farmer, consulted me on Jan. 8th, 1872. She had been ill and under medical treatment without benefit for a year. She was a woman of great energy and spirit, but since her illness she had been very weak and nervous, and unable to attend to her household affairs. Her appetite had gone, and her sleep was constantly disturbed by distressing dreams, during which she often fancied that she was falling down steep precipices or into deep water. After such a night she got up feeling more tired than when she went to bed. She perspired profusely during the night. Of late there had been some œdema of the legs, apparently from debility. There was no evidence of renal, cardiac, or pulmonary disease.

I now inquired for the cause of all this nervous disorder, and it was not difficult to find. She had been in perfect health up to a year before, when one day, as she was driving with her husband in a dog-cart, the horse ran away. Her husband was first thrown out, and after a gallop for some distance along the bank of the Thames, at the risk of being pitched into the river, she was thrown out, and her arm was hurt, but not very seriously. The arm soon got well, but the effect of the mental shock continued.

Having heard this history, I said to her, "If I can make you sleep quietly for a few nights I shall cure you quickly and completely." I then prescribed twenty grains of chloral hydrate to be taken every night, and a mixture, containing quinine, tincture of nux vomica, and hydrochloric acid, to be taken three times a day after food. I saw her again on January 16th. She had taken the chloral for seven nights. She had slept well without dreaming, she had therefore got up refreshed, her appetite and her spirits had returned, and she declared herself quite well. Her sister, who came with her, said to me, "Her recovery is quite a miracle." I replied that it was a simple and natural result of a few nights of quiet sleep and freedom from the harassing terror of the distressing dreams which had so long troubled her. I advised her to take a half dose of chloral for a few nights longer. Her sister called with another patient on February 26th, and reported that Mrs. L—— had continued her medicine for a week after her second visit, that her appetite, her spirits, and her sleep were good, and that she was quite well. I have several times heard since from the friends and relatives of this lady that she has continued in good health.

This case is a good example of a numerous class in which the effect of a sudden violent mental shock is continued and intensified by nightly recurring dreams, during which the brain is worried and exhausted, and the patient gets up feeling more tired than on going to bed. This condition of nervous system, if not removed by remedies, is often continued for an indefinite time until some more serious disorder results.

The following case is an illustration of the terrible consequences which may result if the state of dreaming restlessness, which was so speedily removed in the previous case, is permitted to continue unchecked.

CASE 2.—A. S——, a warehouseman, aged twenty-nine, came to me at the hospital in July, 1851, and said that he was subject to epileptic fits. His intellect was impaired, and he could give but an imperfect account of himself, so I desired him at his next visit to bring his wife with him. She was a very intelligent woman, and from her I obtained the following remarkable history. The husband had always been a sober and steady man, and he never had any serious illness until he became subject to fits, the origin of which she thus accounts for. Seven years ago he was returning with his wife and some friends from Epsom races, when a child in the road accidentally fell under the wheel of his chaise, and was killed. The man was much horrified at the sight of the child's crushed head. That night he started up in his sleep, and called out, "Oh! save the child." He continued thus to call out in his sleep almost every night, and sometimes two or three times in the course of the night. When he started up in this manner he often screamed so as to awaken and terrify his children. At the same time he struggled and clutched with his hands; but when his wife aroused him (which she sometimes had a difficulty in doing) he usually appeared to be quite unconscious that he had been dreaming or making a noise. At other times he complained of having frightful dreams, and, putting his hand to his head, would say that he felt as if he were going out of his mind. Sometimes he exclaimed, "That child haunts me night and day"; at other times, "There is that child again"; and often, when in the street he has seen a child near a horse, he has been in great terror, and his hands have been convulsively clutched. The state of things which I have described continued unchanged for about two years; then he was seized one morning soon after getting up with a sudden and violent fit of convulsions. About two or three weeks after he had two similar fits while in bed, and in about six or seven weeks after this he had another attack. The fits, which are evidently epileptic, frequently recurred up to the date of this history being taken. He has had three or four, and on one occasion, five fits in a day. The longest interval between the fits has been eight or nine weeks. One of the most remarkable features in the history of this poor man is the fact that he had continued to be haunted in his dreams almost every night by the same horrible vision of the child, exciting the same startings up with screams and exclamations. This had occurred, as his wife assured me, so lately as the night before these notes were taken, seven years after the fatal accident. After his epileptic attacks he had sometimes been maniacal, and more than once he had attempted suicide. He had a well-formed head, but his expression was heavy and fatuous, and his memory and his mental faculties generally were much impaired. This sad case had gone beyond the reach of remedies; but what a different history might not this have been if at any time during the two years before the occurrence of the epileptic attacks he had taken for a few nights in succession some soporific pill or draught, which might have broken the habit of dreaming, and thus restored rest to his distracted brain. The history of this case affords a good illustration of the tendency which the habit of dreaming restlessness, when once established, has to perpetuate itself, and to induce other serious consequences.

I will next give you some particulars of a case in which distressing symptoms of very long standing were completely removed by the temporary use of opium at bedtime.

CASE 3.—R. M——, a tailor, was thirty-two years of age when he came under my observation, in October, 1850. He had been a delicate child, but between the ages of nine and twenty-three he had been healthy and strong. At the latter period his father, who had a good business, absconded, taking his money with him and leaving his family destitute; and the son now had to provide for thirteen persons besides himself, including his own wife and one child. From this time he was fearfully harassed, and suffered the usual horrors of intense mental anxiety, restless nights, fearful dreams, spectral illusions, and confusion of thought, to a degree which has often rendered it impossible for him to attend to business. He has often been tempted to commit suicide, and has been enabled to resist the temptation only, as he says, by the force of religious principle. At one time, for a period of two or three years, he was so nervous as to be incapable of taking care of himself, and he had a man to watch him. His habits have always been strictly temperate. This history was obtained partly from himself and partly from his wife, who is a very intelligent and apparently truthful woman.

When I first saw him he was tolerably well nourished, but his face was pale; his expression was torpid rather than anxious; his sleep was disturbed; he complained of great confusion of thought and of "losing himself"; he had a slight cough, and a great dread of consumption. I did what I could to encourage him. I assured him of his freedom from bodily disease, and of my hopes that he might recover. I advised him to take a walk daily in the open air; and on the 28th October I prescribed compound soap pill, two grains every night; and tincture of perchloride of iron, twenty minims, with infusion of quassia, one ounce, three times a day.

On the 11th Nov. the report is that he sleeps soundly, and his appetite has been much better since taking the medicine.

Nov. 18th.—He is looking much better and brighter; he now feels that he can do his work, and he is confident that he will get well. He has had no confusion of thought the last few days. Repet.

Jan. 13th.—He has continued to improve since the last report, and considers himself quite well; his countenance is natural, cheerful, and intelligent; he sleeps well and has neither dreams nor fears; "life is now a pleasure to him instead of being a constant dread." He has no work at present, but he feels quite fit for working. He has continued to take the mixture regularly, but the night pills only occasionally.

March 27th.—Two days after my last report he undertook the management of an extensive tailor's business, which he conducts with ease and comfort to himself, and to the entire satisfaction of his employers. He declares that he never was better in his life, and his wife thinks the same. He looks well and strong. Since the last report he has taken no medicine except an aperient pill occasionally.

In no other case that has come under my observation have symptoms so serious and of such long duration disappeared so speedily and completely as they did in this instance. The improvement, too, was permanent. I saw the man two years afterwards, in March, 1853, when he told me that he was in the same situation, and although the hours were long and the work heavy, he had not been one day absent on account of illness. He slept and ate well, and his countenance was cheerful and intelligent.

I will next give you a brief report of a case in which mere overwork of brain was the exciting cause of nervous symptoms.

CASE 4.—Mr. H. C——, aged twenty-three, articled clerk to a solicitor, consulted me on March 7th, 1872. For several weeks he had suffered from headache, confusion of thought, and inability to work. His appetite was bad, and he complained of uneasiness after taking food. He slept badly, and was much distressed by dreams. The cause of the symptoms in this case was overwork of brain. He had been reading most injudiciously, sometimes from eight o'clock in the morning until two the following morning. When he came to me he had been away for a month's holiday, during which he abstained from all mental application, but he was no better for the change. He had continued to sleep badly, and he was therefore unrested. I prescribed twenty grains of chloral hydrate to be taken every night. He was on his way home when I saw him. He wrote to me on the 16th of March that "for the first four nights he had the most profound sleep, without any dreams; since then he had not had quite such unbroken sleep, but he was thankful to say that he was wonderfully better." I advised him, in reply, if the dreams continued, to take thirty grains of chloral for a few nights, and then gradually to reduce the quantity and leave it off. I heard from him again on March 26th that his sleep was now very good, the pain in his head had ceased, and he intended to return to work that day week.

I wrote lately to this gentleman asking for a report of his progress since I last heard of him. He states that he remained, with quiet work, in pretty good health for some five months, when he had a slight renewal of his old complaint. He took a few doses of chloral and a little rest from work, and then went to Switzerland, where he did some good mountaineering. He returned, read up for and passed his examination, and has stuck well to work ever since, feeling very little of his "old enemy" except "after sticking too closely to work." He goes on to say that he finds plenty of exercise and early to bed the great preventive, but he thinks "the chloral an invaluable remedy." He adds that "after taking the chloral for some time he found no difficulty in leaving it off."

In the next case excessive brain-work with anxiety caused painful symptoms, which quickly yielded to treatment.

CASE 5.—I was consulted a few months ago by my friend Dr. ——, thirty-five years of age, who complained of a painful hyperæsthesia over the whole left side of his body; so sensitive was the skin that even the touch of his shirt gave him pain. He was apparently in robust bodily health, but his nights were disturbed by dreams, and he got up unrefreshed. I knew that he was overworked, and that he was over-anxious. I advised him to take a small dose of chloral at bedtime for a few nights, and I said "a few nights of quiet sleep will rest your brain and remove your nervous symptoms." A fortnight afterwards I received from him the following note:—"Here is an interesting clinical fact. I suffered from hyperæsthesia of exactly one-half of the body—the left side—for nearly a month. Even Brighton failed to cure it. After ten grains of chloral I was much relieved, and after four doses of ten grains on alternate nights, *it has entirely disappeared.* My brain, which has for months felt queer, has got a new lease of activity; I feel ridiculously well, and am amazed at the change. I see now that my ailments have all been due to want of sleep." My distinguished friend has had no return of his unpleasant symptoms; he is now free from anxiety, and his energetic brain is working as hard as ever.

The cases which I have thus briefly described will suffice to convey a general idea of the symptoms which result from overwork, mental strain, and nervous shock. I proceed now to point out some of the more common causes of nervous disorder, with a view to facilitate their recognition by those who are investigating the history of nervous diseases. It will be unnecessary to dwell upon those causes of mental anxiety whose influence is immediately and universally recognised, such as the illness or the death of relations and friends; or, what is often worse than illness or death, the misconduct of those in whom a deep interest is felt, reverses of fortune, failures and disappointments in business, &c. The operation of these causes is so obvious and so powerful as to be seen even by the least observant. We may commonly notice that an overworked man, whether his work be mechanical or mental, becomes an over-anxious nervous man. The overtaxing of the strength is attended by a sense of fatigue and exhaustion, loss of appetite for food, and often by inability to sleep soundly; with this there comes an anxious dread of breaking down, and the combination of fatigue, anxiety, and unrefreshing sleep is a common cause of mental and bodily collapse. And here it may be observed that habitual indolence and neglect of duty often occasion as much mental disquietude as excessive labour and over-fatigue. Those who kill time are not unfrequently

> "Haunted much by visions strange,
> And sore perplexity of roaming dreams,
> The spectres manifold of murdered hours."

The infringement of moral laws brings discomposure and anguish upon the mind as a physical injury gives bodily pain. Some of the most distressing cases of nervous disorder are those which result from the excessive indulgence of the baser animal passions. This is partly a result of the nervous exhaustion and disorder which too often follow upon excessive nervous excitement; partly it is a result of the remorse and self-reproach which torture the man who is conscious of degrading habits. It is scarcely necessary to remark that alcoholic excess will aggravate the effects of overwork, anxiety, and other disturbing influences.

We frequently meet with instances of severe and long-continued nervous derangement as a result of a momentary but violent mental shock. Cases of epilepsy in which the fits have been the result of fright are by no means uncommon. It is a well-known fact that some young and nervous subjects have been frightened into epilepsy by seeing another in a fit. Some time since I heard of two twin brothers one of whom became epileptic. They both continued to sleep in the same room, and the result was that the second soon became epileptic too.

The causes of sudden and violent mental shock are very numerous, and most of them are so obvious as to require no comment. One of my hospital patients (a woman) was excessively nervous long after receiving a fright from the collision of two steamboats, and a false alarm that the boat in which she was a passenger was sinking. I have had several patients who have suffered long and seriously from the nervous shock of a railway collision. One gentleman who was much bruised and shaken in the collision at Harrow Station, in November, 1870, was excessively nervous, and had his sleep disturbed by frightful dreams for several months after he had recovered from the serious physical injuries which he sustained in that terrible crash.

The alarm of fire is a frequent cause of long-continued nervousness. Rather more than twenty years ago the Olympic Theatre was burnt down, and for two or three years after the fire I had several hospital patients, both men and women, who had lived near the theatre at the time of the accident, and who had continued to dream of fire, and to be excessively nervous and timid.

In directing attention to these various sources of nervous shock and mental anxiety, I have acted in the spirit of a suggestion which is contained in the following remarks by Dr. Latham:[*] "Prior to diseases, to their diagnosis, their history, and their treatment, prior to them and beyond them, there lies a large field for medical observation. It is not enough to begin with their beginning. There are things earlier than their beginning which deserve to be known. The habits, the necessities, the misfortunes, the vices of men in society, contain materials for the inquiry, and for the statistical systematising study of physicians, fuller, far fuller of promise for the good of mankind than pathology itself."

The kind of inquiry here referred to, and commended to our notice by Dr. Latham, is, in my opinion, an essential element of a truly scientific pathology, and with reference especially to diseases of the nervous system its paramount importance is indisputable. It would not be difficult to show that many serious errors which have prevailed with regard to both the pathology and the treatment of some of these affections are attributable to a disregard of that portion of the patient's history which precedes the occurrence of actual disease, and a study of which is requisite, as well for the discovery of the true cause as for directing the successful treatment of the malady.

[*] Clinical Lectures on Diseases of the Heart.

Clinical Remarks
ON
TAPPING AND DRAINING THE PLEURA.

Delivered in University College Hospital,

BY BERKELEY HILL,

SURGEON TO THE HOSPITAL.

Gentlemen,—This patient, with fistula in the thorax and abscess in the right pectoral muscle, caused by the escape of pus from an empyema, affords me an opportunity of briefly reciting to you the leading points connected with thoracentesis.

The effusion may be merely dropsical fluid from neighbouring organic disease, inflammatory serous exudation, or pus. To remove these collections thoracentesis may be needed in three groups of cases. (1) In very copious effusions death is threatened by gradual suffocation, but it more frequently takes place suddenly by syncope—a contingency you should never forget. (2) When the effusion compresses one lung, and seriously impedes the action of the heart. (3) When there is hectic or pus it is necessary to open a free drain from the lower part of the cavity in order to gradually close it.

In chronic pleurisy absorption is very slow. Meanwhile the lung is squeezed against the spine, and in time its tissue becomes so much altered that it cannot expand again, or fibrous adhesions grow strong enough to bind down the lung permanently. Such bands also, though less frequently, fasten the pericardium in an unnatural position, by which the action of the heart is hindered. The pleura itself, by long-continued inflammation, becomes very thick. At the post-mortem of the child whose photograph is before you we found the pleura to be one-eighth of an inch thick, making a leathery unyielding cover, fixing the lung to the spine. In this condition, though we had no difficulty in draining the pleura, the lung could not expand to fill up the cavity. In consequence, the skeleton of the child continued to collapse and twist till this extraordinary deformity was produced. Serous effusions after a time are apt to become purulent; in this state they are still less readily got rid of than serum. Pus, too, frequently excites hectic or septic fever, and, by ultimately perforating the pleura, may penetrate to a bronchus or to the surface of the chest, and thus form bronchial or thoracic fistulæ. Spontaneous cure by this means is possible, but, through the indirect course of the fistula, it is tedious.

Formerly a long list of objections were put forward against this operation. Most of them are abandoned; but for the rest a few words of notice may be introduced. Let us take, first, the possibility of wrong diagnosis. Doubtless this cannot always be avoided. But in any case a fine canula and exhausting syringe may be plunged into the chest without the slightest apprehension. Dr. Ringer uses the ordinary subcutaneous injection syringe. This may be inserted in several places if the fluid be not hit upon by the first puncture. Such small wounds of a solid tumour or of the lung itself give no trouble. Bowditch[*] says he has never seen harm ensue even when blood has been drawn out through the ordinary canula. The risk of wounding the intercostal vessels is a bugbear only to the theorist; in practice it does not occur. I do not know that a single case has been recorded, nor has Bowditch met with an instance in 250 cases. It is alleged that to tap while fever is present increases the inflammation. But not necessarily. Dr. Ringer's observations[†] show that the temperature in several cases did not rise after tapping, while when hectic is present, as with our patient of to-day, the temperature rapidly falls after the pus has been withdrawn. Indeed, you may be convinced that no matter what other affections coexist, you will not increase but lessen the patient's sufferings, and help him to recover by drawing away the fluid that harasses him. Be quite satisfied on this point. That fresh fluid is often effused into the pleura after tapping is no real objection. It can be tapped again as often as it collects in any considerable quantity; nor is the absorption of consecutive effusions impeded by withdrawing the first. Indeed, contrary to what was once alleged, repeated puncture is more likely to prevent the conversion of serum into pus than to hasten it. Meanwhile the lung and heart, being frequently relieved from pressure, are less liable to be permanently fastened down in an unnatural position. The entry of air is an objection which has some weight, though it is greatly overestimated. Air has got into the pleura again and again without any mischievous result; but as it is easy to keep air out, that should be always done when the fluid is serous. Whether there is any advantage in closing the wound after evacuating pus is not yet clear; certainly the remainder or any subsequently secreted pus is rarely absorbed spontaneously when the wound is closed. According to my experience, the cavity shrinks and the lung expands only when constant drainage is maintained; thus time is saved by beginning to drain at once. But I must not omit to state that in some of Dr. Ringer's cases the pus gradually ceased to form after simple repeated aspirations; so that perhaps the following rule is the best to lay down for practice. You may simply tap all effusions the first time, unless you have already parietal abscess, hectic, or putrid pus; but on the second tapping, drain the purulent effusions; serous effusions may be simply tapped as often as any considerable bulk of fluid collects.

---

[*] Thoracentesis. New York. 1870.

[†] Practitioner, Dec., 1874.

The mode of operation depends on the nature of the fluid. If serous—and it is probably so when not accompanied by consolidation of the lung or parietal abscess, nor of long standing—it can be reached most readily at the infra-axillary region, and in the sixth or seventh interspace. As you know, in the infra-axillary region the sixth interspace is on the level of the nipple; hence it is easy to select a convenient position for the trocar. This should be plunged in at once without preliminary incision, for the puncture closes, when the instrument is withdrawn, by the elasticity of the skin; but, to make sure, a bit of lint soaked in collodion may be put over the puncture. The quantity to be removed at one tapping depends greatly upon the effect the evacuation has on the patient. There is no advantage in extracting as much as possible, and great pain and even danger at times ensue from doing so. You need not aspirate at all, in most cases; the pressure within the chest will drive out the fluid fast enough, though the syringe is useful to force back a clot or shred of lymph, if such block the tube. Coxeter has lately improved the aspirator by connecting the evacuating nozzle with a long india-rubber tube, by which the stream can run direct to the pan without entering the barrel of the syringe, and the exhausting or injecting power is reserved to overcome accidental plugging. But in most cases I prefer the well-known Thompson's trocar, in which, as you see, the trocar, as it leaves the canula, enters an air-tight stuffing-box; thus air cannot rush into the pleura if the stream ceases to flow out. Under all circumstances let as much flow as will come readily, and stop it if the patient feels a tearing pain or begins to cough violently and continuously—symptoms which Trousseau tells us are caused by the expanding lung drawing air along its disused tubes. Should a second tapping be needed, the patient will readily consent when he has once felt the relief it brings.

When intending to drain, an orifice should be made further back and lower down than suffices for simple tapping. The best situation is that defined by Bowditch—one opposite the lower angle of the scapula, and (in an adult) two inches higher up than the lowest point of respiratory murmur on the sound side. He feels with his forefinger for an interspace, which would be the eighth or ninth, and plunges in his trocar quickly and freely, taking care to go deep enough that he may reach the fluid, through thick layers of lymph, if they be present. When quite sure beforehand that the fluid is pus, use a canula wide enough to let a drainage-tube pass through it; and when the stream of pus flags introduce five or six inches of india-rubber drainage-tube; tie a piece of silk thread firmly to the outer end, and secure that to the skin by placing over it a good-sized disc of diachylon plaster three or four inches above the wound, to prevent the whole of the tube slipping into the cavity—a mishap that has occurred ere now. Then cover the wound with a broad thick layer of tow or tarred hemp, which can be renewed as often as it is charged with matter. In a day or two the quantity will not exceed a few drachms per diem, and is easily managed. Keep the patient as much as possible on his back and injured side, and protect him well from chills, to which he will be sensitive for a long time, and thereby to fresh pleurisy. If the tube first used, being necessarily a small one, does not drain freely enough, in two or three days the orifice will have widened sufficiently to allow a larger tube to take the place of the first. Again, if while the fluid flows the character of the matter induces you to begin drainage when you had tapped with the intention of closing, you may widen the orifice by incising the skin and muscles parallel to the rib while the fluid is running freely, and pass in the drainage-tube by the side of the canula still *in situ*. If you leave the passing of the tube till the chest has emptied itself, you will have much more difficulty in accomplishing its introduction. When there is already abscess in the front of the chest, you may disregard it, and in most cases it is better to do so, and make your aperture at the back as if it were not present. The matter soon drains again into the chest and disappears. A patient put by Sir William Jenner under my care last spring had bulging abscess in the infraclavicular region. The skin was red and fluctuation most distinct. Drainage was made in the back. The abscess shrank considerably even while the pus was running through the canula, and in twenty-four hours all signs of it had disappeared.

With regard to using anæsthetics, certain authorities—Dr. Bowditch, for example—are most strongly opposed to their use. Dr. Bowditch has narrated* to Dr. Clifford Allbutt of Leeds, that in five cases where ether was administered, two died shortly after the operation, a third was restored only by most energetic means, including tracheotomy, and the ether was abandoned in the remainder before the operation was complete. With such examples, anæsthetics should not be used for simple tapping. If the patient dread the prick, the skin may be numbed by ether spray. Nevertheless, when an incision has to be made through thick muscles at the back, and the often tedious operation of introducing a drainage-tube to be undergone, the pain is severe and the shock to the patient in his depressed state proportionately great. In such cases chloroform is given without hesitation in this hospital, and certainly so far without a fatal result. I have notes of seven† cases where I have operated while the patient was under chloroform, large quantities—twenty, thirty, and thirty-seven ounces—of fluid having been withdrawn without any serious difficulty, and in most cases without any unusual symptom whatever. I do not know how often my colleagues have resorted to chloroform, but I am not alone in using it. Dr. Allbutt also remarks that in one of his cases chloroform was employed, and the result was "fairly good." Hence, though anæsthetics are not to be lightly resorted to, they may be safely employed when really required. It is worth notice also that *ether* was the source of mischief in the fatal cases, and that *chloroform* was well borne in our cases.

Lastly, a few words about injections. Boinet obtained great results with them. He used to tap the pleura and inject solution of iodine and close the wound at once, getting sometimes rapidly a complete cure. Used thus I have had no success with injections, and very little in any way. When there is stinking pus and septic fever, an effective drain usually quickly clears off the putrid matter, and the septic fever subsides rapidly. In extreme cases you may wash out the cavity with warm water injected through a flexible catheter, but astringent or antiseptic solutions of all kinds are not wanted, and they annoy or hurt the patient.

Sometimes, owing to adhesions or other loss of expansive power in the lung, there remains permanently a small cavity, which, if kept clear by assiduous drainage, interferes little with the patient's health or occupation. An omnibus-driver, who had extensive empyema three years ago, is now regularly at work, and pays us a visit now and then that we may be sure he keeps up proper drainage of a space that refuses to close completely. He, as well as another patient, who has worked on a lighter up and down the Thames for the last nine years, and is at the same work still I believe, wear a silver canula night and day, through which two or three teaspoonfuls of matter ooze daily. They are both much exposed to the weather, yet are strong and hearty.

---

* Medical Times and Gazette, May 16th, 1874.

† An eighth case has occurred since these "remarks" were made.

The tube must be worn as long as any matter is secreted. One of the patients on whom I operated, a girl, wore it from her eighth to her thirteenth year, during which period she had scarlet fever; yet she is now well-grown, straight, and has very little contraction of the side where she so long had empyema. In concluding, let me mention that when there is great distortion and displacement of the viscera, through collapse of the thorax after empyema, sudden death by syncope may happen. The child whose pleura was so much thickened died thus.

A SECOND SERIES OF

CASES ILLUSTRATING THE TREATMENT OF HÆMORRHOIDS AND PROLAPSUS BY THE CLAMP AND CAUTERY.*

BY HENRY SMITH, F.R.C.S.,
SURGEON TO KING'S COLLEGE HOSPITAL.

Two years since I had the honour of bringing before the Fellows of the Medical Society of London the results of my experience of 300 cases of hæmorrhoids and prolapsus of the rectum operated upon by the clamp and cautery—a method of treatment which I had prominently brought before the profession eight years previously, when I had the honour to deliver the Lettsomian Lectures from this place. The aforesaid results were fairly laid before you in this paper, and, as some of you remember, were pretty freely discussed and criticised. Since that period my experience of this operation has brought my numbers up to more than 400 cases; and now that I have reached this point, and more especially as the experience of the last two years has enabled me to illustrate this operation by cases of greater severity and variety, I have thought it right to furnish you with the information which these additional cases have afforded me. You are aware that I have always contended that the operation by the clamp and cautery, as modified by myself, is a much safer and more satisfactory one than the old-fashioned plan of using ligature. The large experience which I related to you two years ago quite confirmed me in the views which I entertained about this plan of treatment when I delivered the Lettsomian Lectures. I am glad to say that this experience has been shared with me by many surgeons, not only in this country, but in America, India, and Australia; and the manner in which these gentlemen have spoken of the plan of treatment has been most gratifying.

It is not necessary for me to go into the details of the operation which I perform, as they were very minutely pointed out in my lectures, and I believe they are familiar to most surgeons. I will only briefly state that the main feature in this treatment consists in removing the diseased growths or tumours immediately, and arresting or preventing hæmorrhage by the application of the actual cautery. The fixing and removing of the growths are effected by the application of the screw clamp, and the subsequent use of scissors. The operation has the advantage of being completed at once, whereas in that proceeding which had been heretofore so much used, and indeed by some surgeons is used now, by the ligature, the operation cannot be completed at the time, as a given number of days must be allowed to pass before the complete removal of the diseased structures, which have been strangled by the ligature for the purposes of preventing hæmorrhage and causing sloughing and ulceration of the parts involved. This application of ligature to numerous sensitive growths and their subsequent separation are of necessity attended with much local and general disturbance, and when the ligatures separate at the end of a week there is still a large raw surface left, and of necessity the patient is confined to bed or his house for a much longer period of time than if the tumours had been bodily removed at once. However, these matters were freely discussed by me at the time, and they have been freely, and somewhat fiercely, fought over since in this room, and in the journals, and I shall not take up your time to-night in going over the ground again; but, just to show the extraordinary nature of the opposition which has been urged against the operation, I may state that one well-known surgeon wrote a long letter to THE LANCET denouncing the operation. Luckily for me, but most unluckily for himself, the writer let it appear that he had never once made trial of the operation. Another well-known surgeon wrote a book on diseases of the rectum, and so zealous were his efforts to prevent the clamp and cautery operation from coming to the front, that he stated one of the main objections to it consisted in this fact—that the proceeding lasted over an hour. It has often been a source of great amusement to the numerous spectators in King's College Hospital to hear this quotation when they have just witnessed the performance accomplished by me in a few minutes. Of course to such objectors no answer need be made, but others, like my friends Mr. Allingham and Mr. Cooper, have criticised it after having tried it, and such men have a right to be heard, and if they have not seen the merits of the treatment so clearly as I have, I can only hope that their conversion may arrive in time.

And, now, as regards the first and more important point furnished by the present series of cases—viz., the death-rate. When giving the results of my 300 cases, I had to mention the particulars of three cases in which death followed my operation; and, without repeating the details of these cases, I may here state that in all three patients the constitutional powers of life had been so reduced by long-continued hæmorrhage in two, and suspected organic disease of the liver in the third, that the deaths could not be fairly attributed to the particular kind of operation. I was in hopes that, when I presented you with my 400 cases, I might be able to say I had not another death to record; but I regret to state that one death has resulted, and I believe may be fairly attributed to the particular kind of operation performed, and here are the details.

It occurred in the person of a gentleman between sixty and seventy, who had suffered long and painfully from a very severe prolapsus of the rectum, consisting of a mass of mucous membrane and large folds of thickened integument, forming a large tumour. I unfortunately, as I believe now, determined to remove this growth at one operation, and proceeded to use the clamp. I first clamped three portions of mucous membrane high up, and applied the cautery; but, on proceeding to unscrew the clamp, I found one or two large vessels bleeding profusely. Knowing from previous experience that I could stop any hæmorrhage from the rectum by the cautery, I put on the clamp again and reapplied the cautery very vigorously, and completely arrested the bleeding. I then removed the whole of the large external mass with the scissors. The patient bore this severe operation very well, and did not have any bad symptoms the next day; but on the night following he was restless. On the third day he was suffering from abdominal pain, and soon got the anxious face accompanying peritonitis. The symptoms rapidly increased, and he died on the fifth day. Unfortunately, I did not get any post-mortem examination.

Now, on reviewing this case I cannot doubt that the death was due to peritonitis produced by the too excessive employment of the cautery; and I think it possible that I may even have injured the peritoneum, for we know that in some of these very old and large cases of prolapsus the constant descent and dragging on the peritoneum may dislocate, as it were, that membrane, and bring it down much nearer to the anal orifice than natural, and that it may be injured; at all events, if it were not directly injured, the mischief must have extended to it from the adjacent tissue. I was much distressed at this case, for I believe it ought not to have occurred, and I do not think it is ever likely to occur again; for since this event, now just two years ago, I have in such—of which I have had repeated—instances contented myself with clamping the mucous membrane very sparingly, and have been very liberal in removing the external or muco-cutaneous portion of the prolapsus, and in one or two very severe cases I have performed the operation at two sittings—viz., by clamping the mucous membrane first, and in a week or ten days afterwards dealing with the outer part. This case, I am happy to say, is the only instance where death has resulted, and I have had more than ninety cases since this occurred, and cases of the very worst description, where most certainly I should be afraid to use the ligature, in consequence of the mass of tumours which would have to be ligatured, or in view of the shattered state of the system produced by excessive hæmorrhage or other morbid conditions. Indeed, in this last series of cases this morbid condition has been most aggravated, and not without anxiety have I determined to deal with them. I will speak about hæmorrhage connected with the operation by and by, but I may here mention that the anæmia and reduced condition produced by long-continued bleeding is that which is so frequently met with in these cases, especially in ladies. And it is always a source of anxiety, for we all know what a tendency there is for pyæmia to follow a surgical operation when the blood is in the state mentioned. And I may now call to mind a case of a lady sent to me by Dr. Frank from Cannes. This poor lady was like dirty marble, she had suffered so terribly from hæmorrhage; she had also some chest symptoms, and had been told that she must on no account have the bleeding from the rectum stopped. Fortunately she saw Dr. Frank, who begged her to have my opinion. I could not find any active disease in the chest, although she had some spitting of blood, and I at once recommended the operation. Influenced, however, by the opinion already given, she would not consent until she had been seen by Dr. Peacock, and subsequently by Mr. Mac Cormack. Both these gentlemen agreed with me, and I operated, taking great care that she should not lose any blood at the time or afterwards. She made an excellent recovery, and some months afterwards my patient wrote to me saying she had got quite strong, and only expressed her regret she had not been operated on sooner. About the same time a very similar case of a lady who had gone through the most trying bodily and mental ordeals was sent to me by Dr. Fayrer. She also was terribly reduced by hæmorrhage and its sequelæ, but went through the operation as well as the other, with excellent results. These bad cases are those best suited for the treatment by the clamp and cautery, for the hæmorrhage is at once arrested, and the complete sealing up of the vessels produced by the hot iron is, in my opinion, the very best safeguard against pyæmia we can have.

---

* Read before the Medical Society of London.

(To be concluded.)

ANALYSIS OF TWELVE CASES OF PNEUMONIA,

ADMITTED INTO WESTMINSTER HOSPITAL DURING THE MONTHS OF MARCH, APRIL, AND MAY OF THE PRESENT YEAR.

BY F. DE HAVILLAND HALL, M.D. LOND., M.R.C.P.,
MEDICAL REGISTRAR TO THE WESTMINSTER HOSPITAL.

BETWEEN the 4th of March and the 15th of May, or not quite eleven weeks, there were admitted into the Westminster Hospital twelve cases of pneumonia, some of which present special features of interest.

Of these twelve, ten were males and two females, which is a greater proportion of males than usual, the ordinary ratio being as two or three to one; the preponderance of males being accounted for by their greater exposure to vicissitudes of temperature.

If we except two cases on the list—No. 1, a man addicted to drink, and No. 4, a boy of eight, in whom the pneumonia was of secondary importance as compared with the pleurisy—the remainder occurred in early adult life, varying from seventeen to thirty, which is, according to Gunsburg's statistics, the period of life most prone to this disease.

Six of the patients died and six recovered. Of the six who died, two had been addicted to excessive drinking, another had just left the hospital convalescent from pericarditis; of the remainder the previous health had been good. The six who recovered had all enjoyed good health before they were attacked.

Dr. Peacock, in his interesting "Report on Cases of Pneumonia," says that the best measure of the intensity of the disease is undoubtedly the temperature; but out of 32 cases he records in only 3 cases did the temperature exceed 104° F., while in 8 out of my 12 cases the temperature reached or exceeded 104° F. Below is a table giving the number of the case, the highest temperature, and the day and period of day on which it occurred.

No. 2 ...	104·6° F.	on 6th day,	morning.
,, 4 ...	104·3° F.	,, 2nd ,,	,,
,, 5 ...	105·8° F.	,, 2nd ,,	evening.
,, 7 ...	104° F.	,, 9th ,,	morning.
,, 9 ...	104·6° F.	,, 2nd ,,	evening.
,, 10 ...	105° F.	,, 5th ,,	,,
,, 11 ...	104° F.	,, 3rd ,,	,,
,, 12 ...	104·2° F.	,, 5th ,,	morning.

As to situation: of the twelve, nine were on the right side and three on the left. Out of the nine on the right side, the base was attacked in five cases; in one case the two lower lobes; in one the upper and lower lobe, the middle lobe being unaffected; in one the apex; and in one the exact situation was not determined. Of the three cases on the left side, in one the apex was affected, and in the other two the lower lobes.

So much for statistics, and now for a closer examination of the cases, which I shall take in the order of their occurrence.

No. 1.—C. B——, male, aged fifty-six, admitted on the 4th of March. This case was not remarkable for anything very particular. The man had been a hard drinker. He was admitted with signs of pneumonia of the lower two-thirds of the right lung, but there was no expectoration. He was not able to answer questions in a coherent manner, and a few hours after admission fell into a state of low muttering delirium, and died from exhaustion on the 6th. A post-mortem examination was not allowed.

No. 2.—J. C——, male, aged twenty-four. Admitted March 12th; died March 26th. This was a case of pleuro-pneumonia on the right side, which ended in pyo-pneumothorax from the bursting of an abscess of the lung into the pleural cavity. I have not gone into any detail, as the pleural effusion was the chief factor, the pneumonia being of small extent only.

No. 3.—C. M——, male, aged eight. Admitted March 15th; died April 9th. Pleuro-pneumonia, left side, ending in empyema and death from exhaustion.

No. 4.—R. H——, female, aged twenty-one; admitted March 15th. Typical case of pneumonia, affecting the right lower lobe. A fall in temperature of nearly three degrees on the fifth day, but it did not drop to normal till the eighth day of the disease, probably kept up by an intercurrent attack of pleurisy, as she complained very much of pain in her right side, but no friction sound was audible. She was treated with salines, and jacket poultices to the side. Discharged April 10th, perfectly well.

No. 5.—J. A——, male, aged seventeen, admitted March 19th. On the day of admission the following note was made: "Fairly well and at work up to night of 17th, when he was taken ill with sickness, giddiness, and rigors; slept all night and almost all yesterday. Mother noticed that he was delirious this morning. Pupils contracted; no rash; temperature 103·6°; pulse 144, very feeble; heart normal; chest nil. Complains of pain in right side when he breathes, and has pain in the head. Tongue moist, furred, flabby; bowels acted this morning for the first time for three days."

March 19th. — Evening temperature, 105·8°. Ordered carbonate of ammonia, five grains; mixture of acetate of ammonia, one ounce: three times a day. Brandy, four ounces.

20th.—Pulse 136, feeble; temperature 104·2°. Restless during the night, but not actually delirious; eyes suffused; complains of being hungry; tongue dryish down the centre. Bowels acted in the night. Evening temperature, 105·4°.

21st.—3 A.M.: Crepitant râle at apex; no dulness. 11 A.M.: Dull at apex of right lung; heart sounds intensified; tubular breathing; rusty sputa; crepitation at base of both lungs. Morning temperature, 104·6°; evening temperature, 104·9°.

22nd.—Pulse 132; respiration 60; temperature 102·4°. Very delirious all night; rambling now, and trying to get out of bed. Dull right apex in front down to third rib, and to spine of scapula behind; tubular breathing, bronchophony, and a little medium crepitation. Over the whole of the right back there is crepitation, with impaired resonance. Tongue moist, clean. Evening temperature, 105°.

23rd.—Very restless all night; delirious, and trying to get out of bed. Pulse 128, full and hard; respiration 68; temperature 103°. At apex the physical signs are unaltered; the whole of the right back is duller than it was yesterday, with tubular breathing and crepitation. Tongue moist, clean. Bowels acted this morning. Evening temperature, 104·5°.

24th.—Temperature at 1 A.M. 105·2°; pulse 132; respiration 72. At right apex there is now only slight dulness above the second rib, with mucous râles; right back dull all the way down, with tubular breathing and bronchophony. Very restless and delirious all night, trying to get out of bed; tongue red and dry. Evening temperature, 105°.

25th.—Pulse 140; respiration 76; temperature 104°. Right front as yesterday; mucous râles all over right back; restless and delirious all night.

26th.—Pulse 130, intermittent; respiration 56; temperature 101°; countenance livid; pupils dilated; retention of urine, catheter passed; tongue dry and brown; profuse perspiration; involuntary defecation; delirium less violent; floccitation. His friends were sent for, as he appeared to be dying. Ordered three eggs and eight ounces of brandy.—10 P.M.: Temperature 100·8°; no change; passed water voluntarily.

27th.—At 3 A.M. the patient fell asleep, and remained so till 9 A.M., perspiring freely, when he awoke much improved in appearance; sensible when spoken to. Temperature 99·4°; pulse 112, regular; respiration 50. Sputa viscid, purulent, very slightly tinged with blood; no dulness at right apex; rhonchi posteriorly; dulness at base, with crepitation and rhonchus above.

28th.—Morning temperature 98·2°; evening temperature 100·4°.

29th.—Temperature 97·8°. Discharge from left ear began yesterday; no dulness anteriorly; good vesicular breathing posteriorly; resonance impaired at base; mucous râles. Evening temperature 99·5°.

30th.—Pulse 80; temperature 97·8°. Copious discharge from ear; no headache; bladder distended; large amount of water passed. Evening temperature 98·6°.

31st.—Pulse 88, good volume; respiration 34; temperature 97·4°. Resonance only slightly impaired at base, air entering freely; no râles; able to pass water all right. Evening temperature 98·6°.

From this date he continued to improve. On April 5th it was noted that there had been no discharge from the ear for two days. On April 27th, after a most careful examination, the note is, "Resonance impaired above right clavicle; feeble breathing at right apex; no abnormal sounds." Discharged same day well.

I have ventured to give detailed notes of this case as it is an exceedingly good illustration of apex pneumonia. In the first place, he was in a state of great pyrexia for four days before any physical signs of pneumonia were to be detected; this, with the drowsiness, delirium, and contracted pupils, suggested at first the idea of typhus fever. Secondly, I would remark on the extremely violent character of his delirium, and there was no evidence to show that he had been a drinker. It has been denied that the delirium of apex pneumonia is more violent than that met with in other cases where the lung is proportionally affected; but the cases I have seen tend to the opposite conclusion. The pulse-respiration ratio was also very characteristic, keeping pretty steadily, at the height of the disease, in the proportion of rather less than two beats for one act of respiration. Thirty hours before any signs of pneumonia were detected the temperature of the axilla had reached 105·8° F., being a good instance of what Wunderlich would call pneumonic fever. On the sixth day of his illness nearly the whole of the right lung was affected, though the apex was beginning to clear up. Defervescence began on the ninth day, and was accompanied by profuse perspiration and the greatest prostration; but, after some hours' sleep, he awoke quite rational. In this case, as in two others lately under treatment at the Westminster Hospital, the patients have suffered from temporary retention of urine during the commencement of convalescence. Owing probably to some loss of tone and sensibility about the bladder, they allowed it to become greatly distended, and yet, when urged to pass water, they were able to do so.

(To be concluded.)

Medical Societies.

OBSTETRICAL SOCIETY OF LONDON.

THE discussion on the Relation of Puerperal Fever to the Infective Diseases and Pyæmia was concluded on Wednesday, July 7th, Dr. Priestley in the chair.

The PRESIDENT.—We now proceed to the discussion on puerperal fever, which has been adjourned on two or three occasions. It is the general feeling that the discussion should close this evening, and if necessary the time can be prolonged for the purpose. If Mr. Spencer Wells is present, he will have an opportunity of replying. I may add that we are honoured to-night with the presence of two of our distinguished honorary fellows, Dr. Fordyce Barker (who has come from America especially to take part in the discussion) and Dr. Charles West. Dr. Fordyce Barker has explained to me that he has much to say on this subject that may be somewhat at variance with what has been said by previous speakers, and he fears he will scarcely be able to conclude within the prescribed limits. He therefore throws himself on the indulgence of the Society if he transgresses.

Dr. SNOW BECK.—With your permission, Sir, I shall be very happy to concede any right of priority that I may have to the distinguished visitors who are present this evening.

Dr. FORDYCE BARKER.—Mr. President and Fellows of the Obstetrical Society: I feel that I have no right to waste your time in personal topics, except to express my warm appreciation of the honour I have received at your hands, and to appeal to your courtesy to excuse any deficiencies which may be charitably ascribed to weakness of the vocal organs or to the bashfulness which a stranger must feel in addressing such a body of obstetrical men on such a topic as puerperal fever. I may be permitted to say that this discussion is watched with great interest by your brotherhood on the other side of the Atlantic, but that, so far, it does not seem to have led to the happy result spoken of by the Psalmist, "He maketh men to be of one mind in a house." I shall aim, in the remarks which I am about to make, to confine myself closely to a discussion of the questions now before us, and to state my opinions, and the reasons which I have for holding such opinions, in the most terse, compact language compatible with clearness. If these opinions seem to be in antagonism with the great majority of those which have been expressed, I ask that they may not be regarded as partisan in their tone, but as a presentation of views necessary for a full and comprehensive study of the subject. I ask that the arguments urged may receive that candid analytical sifting requisite for a sound decision as to what is the true answer to the questions now before us. I concede to all, and I ask all to concede to me, that it is the truth, and not forensic success, which is sought for by all who speak in this discussion. I cannot suppose that the proposer of the six questions intended that all of us should accept each of these questions with all the qualifying phrases. Of the six questions proposed, the second and third only admit of the categorical answer of "yes" or "no"; and this will be one or the other, depending upon the answer given to the first question. If the first question be answered in the affirmative, the answer to the second will be in the negative, and the answer to the third will be in the affirmative; or the answers to all three of these questions may be exactly the reverse. I suppose the meaning of the first question, as defined by the second and third, to be: Is there a disease peculiar to women after childbirth never met with under any other circumstances, as distinct as typhoid or typhus fever, scarlet fever, measles, or small-pox? I do not suppose that the proposer of these questions intended or thought that all who believed that the first question could be answered in the affirmative, that puerperal fever is a distinct disease, must therefore accept all the qualifying phrases. "Distinctly caused by a special morbid poison" is one of these qualifying phrases. Is this considered an essential characteristic of a distinct disease? Has science yet determined what the special morbid poison of typhoid fever is? If the phrase had been "*often* caused by a special morbid poison," I should have accepted it as true of puerperal fever, as I believe it to be true of diphtheria and several other diseases. A disease caused by contagion or infection is distinctly caused by a special morbid poison; but there are many diseases which result from multiple causes, of which I may mention diphtheria, typhoid fever, and others. It is just this phrase which seems to have debarred Dr. Farre and Dr. Richardson from answering the first question in the affirmative; and it is just the idea involved in this phrase which seems to have caused much of the obscurity and ambiguity in its discussion. It implies that a given cause—a special morbid poison, if you please—which produces a distinct disease, must always result in this distinct disease. Is this the case with numerous other diseases? In a wealthy family belonging to my *clientèle* I saw, a year ago, a lady dangerously ill with pyæmia, in consultation with Dr. Sayre, who was attending her for a severe traumatic injury. At our suggestion a careful examination of the house was made by a plumber, but no defect could be discovered which could explain the source of the blood-poisoning. Soon after, three of the family, one after another, were taken ill with a typho-malarial fever. I even insisted that the walls of the room should be torn down, when it was discovered that a leaden waste-pipe had defects which permitted noxious gases to permeate the house, but which were not sufficient to permit the escape of liquids to stain the walls. During the past winter I attended a gentleman with severe typho-malarial fever. His residence was in a large house constructed on the plan of the French apartments. This house was entirely occupied by families of wealth and refinement. During his convalescence diphtheria appeared. In another family in the same house I saw in consultation the first child attacked; afterwards the father and two other children, one of whom died, were attacked with the same diphtheria; and it is worthy of mention that the mother, who was removed from the house during the illness of the others with diphtheria, was confined with her fourth child under the care of Dr. Stone, one of our prominent physicians, and that her convalescence was not impeded by any puerperal disturbance either from diphtheria or typho-malarial or puerperal fever. On examination, it was found that the waste-pipes in this house were in precisely the same condition as the house I before mentioned. At the last meeting of the Society Dr. Playfair related some facts of recent occurrence at Notting-hill, where septicæmia in the wife, from which she barely escaped with her life, and diphtheria in her husband, seemed to be due to the same class of causes as that which produced the disease in the case I have mentioned. I ask you to note the language used by Dr. Playfair in relation to these cases. He says, "Who can doubt that these two diseases were caused by the same septic poison?" One of these diseases he names, from his theory in regard to the cause of the disease, septicæmia; the other, from its clinical phenomena, he names diphtheria. The idea involved in this phrase, "distinctly caused by a special morbid poison," implies that it results from only one cause, and that this cause must always be followed by identity of result—that if the poison is known to produce any distinct disease, then this disease must always follow the cause. The second qualifying phrase, to which I will simply allude and not discuss in detail, is, "distinct in its progress and the local lesions associated with it," as certain diseases specified. I have only to say in regard to this, that it seems to me that the several diseases mentioned differ in degree as to the definiteness of their progress and as to the definiteness of their local lesions, and that consequently puerperal fever cannot be compared with these diseases as a group in these particulars. I will now give my reasons for believing that puerperal fever is a distinct disease occurring to women after childbirth only. I think the definition given in the nomenclature of diseases emanating from the Colleges of Physicians and Surgeons is absolutely perfect: "a continued fever, communicable by contagion, occurring in women after childbirth, and often associated with extensive local lesions, especially of the uterine system." It is a disease which results from the absorption of poison causing various blood changes, independently of local lesions, which produce certain general characteristic constitutional symptoms. I need not discuss this point in detail, for from what has been said it is evident that localism or Broussaisism has no status in this Society; and those who believe that this is only a disease resulting from septicæmia and those who believe it is a continued fever are in agreement on this point. We can arrive at truth in medical discussion only by using language accurately. There can be no accuracy of idea without accuracy of language. The established usage of standard authorities in medicine is to designate as fevers all that class of diseases which, from the absorption of some poison in the system, independent of local lesions, produce certain blood changes, and also cause certain general characteristic symptoms; so that under this designation are properly and legitimately included not only those diseases severally called typhus, typhoid, relapsing, intermittent, remittent, and yellow fever, but all those constitutional and infective diseases which occur epidemically and endemically. When the specific poison is known which causes these constitutional diseases as the result of blood changes, then the name of this poison is given to characterise the disease, and we have as accepted terms, uræmia, septicæmia, pyæmia, and others of a like character. I will simply remark here that none of this class of diseases, so far as is known, ever occur as an epidemic or are contagious. The point that we are trying to settle is not a question of name, except so far as this: I take it that we are all agreed that the name given to a disease should be significant and appropriate. The gist of the matter, stripped of all its superfluous and obscuring elements in the inquiry, is whether there be a distinct disease which occurs in puerperal women, and in puerperal women only. The answer to this question can be derived only, as I believe all will agree, from three sources—from studying the causes, the clinical phenomena, and the pathological anatomy. I do not think that much information can be derived from studying the causes of this disease in order to settle the question under discussion, any more than there can be in settling the question from studying the causes whether typhus fever, relapsing fever, and diphtheria are distinct diseases. The study of the causes is of vast importance in a sanitary point of view, and hence I regard the paper which was read by Dr. Braxton Hicks before this Society several years since as a most valuable contribution to the subject. I think no one doubts that if a woman after confinement be exposed to the poison of scarlet fever or that of any other infectious constitutional disease, she will have scarlet fever or whatever disease she absorbs the poison of. I do not understand Dr. Hicks to claim that puerperal fever is only scarlet fever in the puerperal woman, but names this as one of the causes in the same category with diphtheria, erysipelas, mental emotion, and so forth. I think the evidence is conclusive to the vast majority of minds in the profession, established by numerous incontestable facts, observed not in sporadic cases only, but in numerous epidemics and in epidemics which have not occurred alone in hospitals and large cities, but which have ravaged large tracts of country in sparsely populated rural districts, that the poison of erysipelas may cause in women after childbirth a distinct disease which some of us choose to call puerperal fever, and that the poison of puerperal fever, if absorbed into the system of a man or a child, will cause in that man or child erysipelas. I need not refer to the medical history of Great Britain in proof of this assertion, but I perhaps may be permitted to refer to that of my own country for corroborative evidence. A reprint of "Nunneley on Erysipelas" was published some thirty years ago, with notes by Dr. John Bell of Philadelphia, in which he gave facts showing the intimate relationship between erysipelas and puerperal fever in numerous epidemics which prevailed extensively over the United States. During the past year a valuable monograph on erysipelas and child fever, by Dr. Thomas C. Minor of Cincinnati, Ohio, has been published, which I had the opportunity of reading on my voyage over. The book is based on a most painstaking and laborious study of the vital statistics of the Census of the United States for 1870 and an epidemic of puerperal fever which prevailed in South-Western Ohio in 1872, and I think it is worthy of careful perusal by all who seek to influence medical opinion on the subject of puerperal fever. A careful study of these statistics does not seem to show any intimate relation between typhus fever, scarlet fever, pyæmia, septicæmia, and puerperal fever. An epidemic of scarlatina was rarely followed by an outbreak of epidemic puerperal fever, but an epidemic of erysipelas was invariably attended by an outbreak of epidemic puerperal fever. The argument that puerperal fever is not a distinct disease rests mainly on the ground that it is simply due to a septic poison. Septic poison is a term now frequently used, and often very vaguely, but those who claim that puerperal fever cannot be regarded as a distinct disease do not claim that all disease which results from the absorption of septic poison must be one and the same thing, and that this should be called septicæmia. Is there anything improbable or unphilosophical in the hypothesis that septic poison acting on the system in a peculiar state, which never occurs in the human system under any other conditions—that state so graphically described by Dr. Richardson and Dr. Farre in this discussion, — should result in a distinct disease which never occurs except when the system is in a special condition? The answer to this question is to be found in the study of the clinical phenomena and pathological anatomy of the disease. If septic poison never occurs as an epidemic (I do not say an endemic) among those who are suffering from traumatism, and is never contagious under these circumstances, and if septic poison in women after childbirth does occur as an epidemic, and is contagious and infectious, are not these two elements sufficient to warrant us in regarding this as a distinct disease? Those who believe that puerperal fever is only septicæmia have seen that they must accept this issue, and have been driven to deny that puerperal fever ever occurs as an epidemic or that it is contagious. If in a given territory women after childbirth die in proportion to the births in numbers fiftyfold or a hundredfold greater than they have died for several years previously, or than they die for several years following, would we not in common language say that an epidemic prevailed in that district? When, in four months of the year 1873, in that part of New York which is in the best sanitary condition of any part of the city, in which the most wealthy portion of the population reside, the number of deaths from a disease—call it puerperal pyæmia, puerperal septicæmia, or puerperal fever, as you please—is twenty times greater than it had been for twenty-five years previously, and double what it is in other portions of the city in much worse sanitary condition, where the poor women are crowded together in their houses, and quadruple what it is at the same time in the lying-in hospitals of the city, are we not justified in saying that an epidemic prevailed in the city at this period? When in Cincinnati in 1872 the deaths from this disease were 122, while the annual average of deaths from this cause for the five previous years had been $13\frac{3}{5}$. can we not properly say that an epidemic prevailed in Cincinnati at this time? In view of all the material abounding in medical literature, and such facts as these, I will not borrow a phrase from one of the speakers at the last meeting, and say that those who deny that this disease occurs as an epidemic must have minds which are not open to conviction; but I will say that they must attach a subtlety of meaning to that word "epidemic" not consonant with common sense. Please to observe that I do not use the definite article, and say "the common sense"; otherwise the phrase might be discourteous. I will now submit the three following propositions:—1. The clinical phenomena of puerperal fever are quite different from those of surgical septicæmia or surgical pyæmia. 2. These affections do occur in puerperal women, and the result is a disease which does not constitute a continued fever communicable by contagion. 3. When either of these affections complicates puerperal fever it modifies the clinical phenomena by symptoms which can be distinctly appreciated and accurately described by any careful observer. I will not give the evidence on which these propositions are based, because I think that this has been done in a work on Puerperal Disease which it would be indelicate in me to speak of in more definite terms. I will say but a few words with regard to the pathological anatomy of the disease. Dr. Richardson argued, at the first meeting of this discussion, that there are no local lesions which will permit us to say of a case in a dissecting-room, "This is a case of puerperal fever," as we would say, "This is a case of scarlet fever, or typhus or typhoid fever." I think it would be extremely difficult to prove that there are local lesions which have established the fact that scarlet fever, typhoid fever, and relapsing fever are distinct diseases. I will not illustrate this by the subject of scarlet fever, for I find that my time is fast going; but I will simply ask, Would any of the most recent authorities on the continued fevers—would Sir William Jenner, or Dr. Murchison, or Hoffman, or Lebert—insist that a disease could not be registered as typhus or as relapsing fever, except certain anatomical lesions could be demonstrated in the dissecting-room as determining this disease? All these authors agree that these diseases, which we accept as distinct diseases, have no pathognomonic anatomical lesions. The author of the address on Obstetric Medicine before the British Medical Association last year asserts that pathologists have torn in tatters the view that the disease which we are discussing is an essential fever peculiar to puerperal women, as distinct as typhus, or typhoid fever, or scarlet fever. When? Where? How? Give us the proof that any such pathologists have ever studied this disease, except in hospitals and large cities, where it is probably complicated with pyæmia and septicæmia. Of what value would be the researches of the ablest pathologists of Germany or England on questions relating to the pathology of yellow fever if such pathologists had no opportunity of studying this disease except in Germany or England? Has Spiegelberg, or Schroeder, or Schruechberg, or Mayrhofer, or Orth, or Heiberg, or Olshausen, or Fehling, or Cohnstein, or Breisky, or von Haselberg, ever studied puerperal fever as it is found in epidemics in rural districts where pyæmia and septicæmia are rarely met with? German is a difficult language to acquire, and it gives an attractive appearance of learning to introduce such names, even if nothing be quoted from them. I am familiar with their writings, and would not undervalue their researches; but so far as the elucidation of the question now under discussion is concerned, I think it of equal importance that we should carefully study, for the clinical phenomena of the disease, your English classical writers—Hulme, Leake, Kirkland, Clarke, Gordon, Hey, Armstrong, and Robert Lee. The hint on this point thrown out by Dr. Farre at the last meeting seemed to me most appropriate and timely. What progress is made in science—how do "we free ourselves from error," or gain in scientific precision or accuracy of description, in giving to this disease a new name—pyæmia, as Dr. Duncan would call it, while he confesses that it has no etymological signification in this disease, and in fact has no definite, positive meaning? What propriety is there in giving to an obstetrical disease a name significant and appropriate to a surgical disease, unless it can be demonstrated that the two diseases are identical in their clinical phenomena, and their anatomical lesion? The burden of proof to show this identity belongs to those who would call the disease puerperal septicæmia. Some think the negative has already been established. I have neither the time nor the voice to discuss the other questions which have been proposed. With my warmest thanks for your courtesy in listening to me so patiently, allow me to close with the suggestion that it may be well for all of us who discuss puerperal fever to remember the exhortation of Oliver Cromwell, when he lost patience with a Scotch Assembly, "I beseech you, brethren, by the mercies of God, conceive it possible that you may be mistaken."

Dr. WEST.—I came here to-night because I felt that honour implies duty, and having now for some years had the honour of being one of your fellows, I felt that if on the occasion of so important a discussion as this I stayed away, it would seem either as if I cared nothing about the exercise of my profession or about the furtherance of it, or as if some other motive—I know not what—had kept me away from your assembly. What I have to say I will say in as few words as possible. And first of all I have but one criticism to offer, and that bears on one of the questions which have been suggested with reference to the share that certain microscopic organisms have, or may be supposed to have, in the production of the disease called puerperal fever. It appears to me, with all respect to the gentleman who in his able paper proposed that question, that it is somewhat out of time to raise it. We have not as yet a sufficient amount of knowledge on the subject to be able to apply it or to draw from the observations that have already been made any correct and useful inference; and no one, I think, can have read with care the very interesting discussion on the subject of the germ theory of disease without being struck by the way in which men of the greatest talent and the sincerest love of truth differ not merely with reference to the conclusions that they drew, but also with reference to the very facts that they thought they had observed. I think, Sir, if this matter is to be settled, it must be settled, in the first place, in the case of some disease simpler in its nature than puerperal fever. I pass, then, from that in these few words, in which I would wish still to convey the very high respect I feel for a kind of knowledge to which I can make no pretension, and to assure you that what I have said means no disparagement to the study carried on by means of the microscope, nor any doubt of the great results that hereafter we may arrive at from them; but I refer to it from the conviction that the question so raised is, in the case of puerperal fever at least, premature. I now approach the other and more practical questions. It may be allowed me, perhaps, to remind the Society of what I doubt not they have not forgotten—that some thirty-six years ago a physician, now taken from among us, but whose professional chair it was my honour for a short period to occupy, wrote a work on the very subject which we are now discussing, and I do not myself see that we have advanced far, if at all, beyond the conclusions which Dr. Ferguson had laid down, that the phenomena of puerperal fever depend upon a vitiated state of the fluids, and that in the condition of a woman in the puerperal state, such vitiated state of the fluids is specially apt to arise. I do not think, therefore, Sir, that we can in any way assimilate the condition of what is called puerperal fever to typhus, typhoid, or scarlet fever. The disease wants those characteristics which more or less distinctly prevail in the case of the specific fevers. It has not the same regularity of course, the same regularity of incubation, the same regularity of outbirth. It has not the same diagnostic marks which we find in the case of the specific fevers, such as the pustules which appear, even though in small number, and characterise even the slightest case of small-pox. Nor is this all; but with reference to these fevers we know further that, for the most part at any rate, they produce a disease like to themselves, and that, though with many exceptions, they have a tendency not to recur where once they have happened. Now all these characters are absent in the case of puerperal fever; while the very circumstance that a far greater proportion of cases of puerperal fever occur in primiparæ than in those who have given birth to many children shows that there is a marked connexion between the liability to an outbreak of the disease and the difficulties attendant on the process of labour. If, further, one exposes a man to the contagion of puerperal fever, he does not get any disease as the result of it. If we expose a woman in the puerperal state to the contagion of scarlet fever, measles, or some other disease, she may have that disease, even though its characters may be masked and altered in some degree by the puerperal state. But it does not necessarily follow that she will have that same disease. In the cases related by Dr. Collins, of Dublin, with reference to two epidemics of puerperal fever, the introduction of a case of typhus fever into the hospital was followed on each occasion by an outbreak of puerperal fever. So it would seem that a cause distinct from anything which we can identify as the special poison of puerperal fever may yet, by the influence which it exerts upon the woman in this peculiar condition, produce a disease not distinguishable by any of its phenomena from that assemblage of symptoms which we ordinarily call puerperal fever. It seems as if the puerperal state was the condition of the development of this set of symptoms. Moreover, we must remember that there is not one single solitary cause to which we can refer the symptoms of puerperal fever; that it occurs now from one cause and now from another. I remember at this moment the case of a lady in a state of perfect health who was delivered at a time when puerperal fever was prevalent. She was a person in that position in society in which she was shielded from every possible danger. Soon after her delivery she was exposed to a current of air and caught cold. In a short time the symptoms of puerperal fever developed themselves, of which she died. Here was a case in which there was no special morbid poison existing—nothing but what could be derived from her own fluids or brought about by some impression on the system. Moreover, we know that mental shock will have the effect of producing the symptoms of puerperal fever, leading to a fatal issue. I remember the case of a lady who progressed perfectly well after an easy labour, but owing to some violent scene of domestic strife with her husband, she was seized almost immediately with symptoms of puerperal fever, at a time when no such disease was prevalent, and of that disease she died. I think, then, we are to look for the cause of puerperal fever rather to the condition of the person after delivery than to any special poison. Poisons of various kinds may produce it. We know that in Vienna puerperal fever was exceedingly prevalent, owing, as was discovered, in a great measure to the fact that the students left the dissecting-room and went with their hands imperfectly cleansed to attend the women in their confinement; and when greater care was taken, when careful ablution and disinfectants were insisted upon, puerperal fever diminished in its frequency to a very great extent. We know that local violence may produce it; in short, we know that a great number of cases may give rise to it, and that the only one factor in the production of that class of symptoms consists in the special state of the woman after delivery. That state I need not recall. It is a state in which the fluids are laden with old, effete, and useless materials, out of which the old uterus is removed and a new one is to be built up; they are laden also with those elements out of which eventually the new secretion of milk is to be established. None of us, except those few who, like Dr. Richardson, have given great attention to these inquiries, can describe at all wherein the alteration of the blood consists; yet, without indulging in any wild theory, we may say that there is a something—people used to call it a ferment; I do not care what it is called, provided we use the name, not as defining the thing exactly, but as a name only to which we attach no other meaning than that of a something by which we are to distinguish this or that from the other, while as yet we know not its real nature. For instance, in the time of the old alchemists, calomel and corrosive sublimate, the chemical composition of which was unknown, were respectively called Draco magnus and Draco mitigatus; and if we use names as the old alchemists used theirs, we shall be much more likely to keep from the error of hasty conclusions or rash generalisations than if we use a name to which we tack a definite scientific meaning while as yet we have no sufficient grounds to rest that meaning upon. Those were the chief things which, it occurred to me, might perhaps be worth the saying. Take a woman in the puerperal state in whom is checked in any manner, whether by poison from without, by mental shock, by cold, or injury, the regular performance of those functions that ought then to go on, and you have the condition thereby produced out of which the assemblage of symptoms that we call puerperal fever—and all the world is pretty well agreed to give it that name—arises. The only other word I would utter is, to quote a saying of a great, wise, old physician, who said that the highest aim of our art must be the greatest possible generalisation of diseases and the greatest possible individualisation of our patients, so that we have in each case to look to the prevention of puerperal fever, not simply to the removing of the possibility of contagion, not simply most carefully watching the local condition of the uterus and removing from its inner surface any possible decaying matter, not simply to the taking care that the air that surrounds the patient is good, but we are bound also to consider the patient's mental state, to regard minutely her individuality, and, if we wish to put a stop to the disease, to remove from around or from within our patient anything which can interrupt those important processes the interruption of which gives rise to those symptoms which we designate by the name of puerperal fever.

Dr. Snow Beck.—I never had so strongly the feeling that I would have been glad to escape from the position in which I may have been placed as I do this evening, after hearing the very learned and eloquent addresses with which we have been favoured; but I feel emboldened by the sentiment with which Dr. Fordyce Barker concluded, that possibly we may yet all be mistaken, to state the conclusion to which I have been led, chiefly from my own observations, upon the nature of the diseases which at present engage our attention. These observations have led me to a conclusion directly opposed to the opinions expressed by the previous speakers, for I am unable to perceive that there is any special or specified disease connected with childbirth, or to which the term puerperal fever can be properly applied. I must be also bold enough to contend that the definition published by the Nomenclature Committee of the College of Physicians cannot be maintained in practice, for I have never yet been able to make out "a continued fever, communicable by contagion, occurring in connexion with childbirth, and often associated with extensive local lesions, especially of the uterine system," which is essentially connected or associated with the condition of the system after parturition; or, in other words, which is not met with at any other period of the woman's existence. With reference to this definition, Dr. Arthur Farre informed us that the word "communicable" was only intended to convey that it might be communicated, but that it might also have a spontaneous origin, and the word "often" was only to call attention to the frequency with which these complications arise. Dr. Farre added that the Nomenclature Committee were entirely at a loss where the term puerperal fever ought to come in the catalogue of diseases. It was not placed among the fevers at all, but amongst the general diseases far away from the fevers, finding a place of refuge at last at the bottom of the list, after pyæmia, erysipelas, &c. But why should the Nomenclature Committee be in any such difficulty if there really existed any continued fever, communicable by contagion, specially connected with childbirth? Whilst admitting this difficulty, however, Dr. Farre said he was not prepared to admit there was no such disease as puerperal fever; he should be sorry to shut out the idea as one that is impracticable, and not to be entertained. If we are to look for a puerperal fever at all—one that can be properly so called, a disease which is *sui generis,*—we shall probably find it in the interruption to those healthy processes going on in the lying-in woman: first, the milk process, the milk secretion, and that attendant disturbance of the constitution which we term milk fever; and, secondly, a much more important one, the change which goes on in the uterus, and which we all know as the involution process. "Now we know," continued Dr. Farre, "that when this process is interrupted there is an arrest of all the eliminative action which the involution process implies; and we may fairly conclude that in consequence of this arrest there is some accumulation in the body of those effete matters which ought to be expelled from the system, and this, added to the existing blood dyscrasia, must very much aggravate the disease." But may it not be replied that this sounds very like admitting that up to the present time no such special or *sui generis* disease has been recognised? If such a disease be developed in the changes which take place after the birth of the child, why has it not been found and described during the years of diligent study which so many of our most able and acute physicians have devoted to the elucidation of these diseases? and why is it that we have got no further than the unsatisfactory statement, that if we are to look for a puerperal fever at all we may probably find it in some arrest of these healthy processes? What proof, it may be asked, is there that in the serious and fatal diseases following childbirth there is any interruption of those healthy processes which go on in the lying-in woman—any arrest of this assumed eliminative action? Supposing, however, for a moment that such an interruption or arrest should take place, what proof is there that this arrestment would create in the system so serious a disease—a disease *sui generis,* and capable of being communicated by contagion? It must not be forgotten that the growth of the uterus is a healthy physiological process, that the tissues which are formed are perfectly healthy tissues. When and where have there been any facts observed which justify, or even countenance, the supposition that the retention in the system of any portion of a healthy tissue will generate such a disease that the majority of the women in whom it becomes developed will die? I am not aware of any facts upon which the least reliance can be placed which justify the inference that such a disease-creating action is even probable; and I must add that, instead of speaking of it as possible or probable that such a *sui generis* disease would be found if looked for, would it not have been more satisfactory, and certainly more conclusive, if the symptoms which would indicate such a disease during life had been given, or the appearances in the dead body described, by which its previous existence might be affirmed. So far as my knowledge extends, no reliable facts have ever been recorded which show that any such *sui generis* disease has been observed in practice, nor can I think that anything is gained by substituting the term post-partum fevers for that of forms or varieties of puerperal fever, for these terms are evidently intended to denote the same class of morbid phenomena, whatever their nature may be. In further considering these questions, I must contend that the process of childbearing is a natural function in the female, and that nature has provided her with all the powers requisite for the complete performance of this function as a part of her natural endowments. Every day's experience appears to exemplify this fact, not only in the human female, but also in the female of all other animals; yet, on the other hand, no one doubts that the peculiarities of the system after parturition modify to a certain extent any disease which may have existed previous to the confinement, or which may have commenced subsequently. But I am not aware of any observations which support the notion that there is anything in these conditions which, in a healthy female, is the source or element of disease, or which in any way can alter, or has altered, the essential nature of any disease with which she may be attacked. All women, however, are not in health when they become pregnant, and consequently are not in health at the birth of the child; and many women are not endowed by nature with the constitution and formation favourable to the propagation of their species. Women in either of these categories must necessarily suffer from different diseases, and from various causes, after parturition; but the fault is here with the individual, and not with the natural and physiological process of procreation. But if it be true, as I believe it is, that there is not any disease specially connected with childbirth, it must not be forgotten that the converse is equally true, that there is not any disease from which the lying-in woman is exempt; in other words, that the condition of the system induced by pregnancy, or that which follows after parturition, does not prevent the existence of any other disease which may attend the female at any other period of her existence. Hence we must be prepared to meet with, in the lying-in woman, any of the diseases which flesh is heir to, and the diseases so met with become naturally divided into two classes—one class arising from the general system, and being the result of changes and accidents to which all women are liable at any period of their existence; the other class arising from the uterine system, and being the consequence of accidents incident to pregnancy or childbirth, yet not comprising any disease specially connected with either of these states. When speaking of these diseases, Dr. Farre observed that he had been in the habit of dividing what he termed post-partum fevers into three classes. First, those irritative fevers arising from some local irritation, and not implying blood infection of any kind, pyrexial states of a fugitive and transient nature, resulting from simple mammary irritation, slight injuries to the soft parts, laceration, and the like. Second, under the name of the milder forms of infective fevers would be classed all those in which the infection is not of a specified nature, in which the process does not undergo a period of evolution, a period of development, and in which the consequences follow no definite order. Thirdly, the eruptive fevers, and those which depend upon a blood infection, the poison following a specific course, having a regular period of incubation, and terminating in those several diseases, eruptive fevers, and the like, which occur of course in the lying-in woman in common with others. In glancing at the different diseases met with after childbirth, it may be well to do so under these heads. First, then, it would appear evident that those pyrexial states of a fugitive or transient nature, which are met with in almost every woman who has been confined, cannot be classed as belonging to the same category as those serious and often fatal diseases which follow parturition or abortion. We might as well include all the diseases in the nomenclature of diseases, for every one of these might, by possibility, be met with in a woman recently confined; yet it is singular how often these trifling and transient affections have been considered as the commencement or form of serious disease. Dr. R. Ferguson, in his admirable essay on Puerperal Fever, wherein he correctly attributes the most serious diseases to a vitiation of fluids, though the nature and source of this vitiation are not so clearly stated as perhaps they might have been, remarks (p. 101) that a dose of salts-and-senna so invariably brought on metro-peritonitis that he forebore the use of this drastic irritant as a routine dose; also (p. 16) that during a reputed epidemic of the peritoneal form, after two doses of Dover's powder of ten grains each the patients did not require any other treatment. Secondly, it is well known that the lying-in woman is often exposed to, and not unfrequently attacked with, the eruptive fevers or acute specific diseases. I believe that every one of these diseases has been met with at one time or another, and we cannot deny the proofs that they have been communicated by the nurse in attendance, and possibly, though very rarely, by the medical attendant. We all know that these diseases exercise a great influence, though in different degrees, upon the pregnant uterus. The rules under which women are received into the different lying-in hospitals when the pains of labour have commenced, and often during the night, give great facilities for the introduction of these diseases. Various instances are recorded where typhus and other fevers have been so introduced into lying-in hospitals, and have spread from patient to patient, constituting a so-called epidemic. It is recorded that on one of these occasions, after the introduction of a case of typhus fever into the Dublin Lying-in Hospital, "puerperal fever appeared in forty-eight hours afterwards, although the hospital had been free from it for a year before." But the disease which thus became developed was no doubt typhus fever, for evidence is entirely wanting to show that any of these infective or acute specific diseases have ever been known to change their nature. Some of the symptoms usually characteristic of these diseases may have been masked, or possibly absent, in some instances, but their specific nature has in no way changed. I cannot place any confidence in the statement that all these infective fevers "are excessively prone, if brought near the lying-in woman, to originate puerperal fever"; or that, by some wonderful and potent influence in a woman recently confined, all these different specific diseases are transformed into one and the same disease. Dr. Braxton Hicks appears to draw some subtle, and to me incomprehensible, distinction between puerperal diseases and puerperal fevers, and has carried this transmutation of diseases even further than those who have preceded him. He imagines that a disease not only changes its nature when it enters the system of a woman recently confined, but when it again leaves her system and enters into that of another—to quote his own words—"it becomes reconverted into the zymotic form whence it had sprung." The experience, however, which has been adduced by the different fellows during this discussion appears conclusive that these eruptive fevers do not become changed in any respect when developed in a woman recently confined; and I feel assured that Dr. Arthur Farre correctly stated the fact when he said, "I do not consider these diseases as in any way taking any part in the puerperal fever." Nor is there any evidence, such as in a scientific point we have a right to require, that the same cause can produce directly different results in different individuals—such, for example, as that mentioned by Dr. Playfair, where the same cause, included under the very vague term of "unhygienic condition" of the house, is said to have produced diphtheria in the husband and puerperal fever in the wife. I must admit to having a mind "not open to conviction" by such tales, where the effects supposed to have been produced are contrary to everything that has been observed in the course of nature or in disease, and where the statements rest only on the imagination of the narrator, unsupported by sufficient facts. Thirdly, all these diseases of the general system which have been adverted to are of minor importance, as only a small minority of them prove fatal. They evidently do not constitute that serious class of diseases which come on so insidiously, continue gradually from bad to worse, and so frequently end in death, that, as Dr. William Hunter said, "treat them in what way you will, at least three out of every four will die." These diseases, which have invested the term "puerperal fever" with such fearful significance, arise from the uterine system, and are included in Dr. Farre's second class, though I feel assured he has erred in supposing they are "infective fevers," or can be termed "the milder forms of infective fevers." They really constitute the serious, and too often fatal, diseases which are met with after childbirth. Let me sketch a case as illustrative of the class of diseases referred to. A healthy woman, after a natural confinement, with or without hæmorrhage, remains very well for two or three days, then has a rigor, which is followed by a very frequent and feeble pulse, a feeling of great prostration and sinking, some pain across the lower part of the abdomen, with considerable tenderness when pressed, gradual swelling of the abdomen and tympanitic resonance, considerable thirst, some sickness, with loose, offensive motions. Gradually the patient becomes weaker and weaker; some shortness of breath, with slight cough and expectoration, is noticed; and she sinks after two, or it may be three, weeks without more marked symptoms. After death the peritoneal cavity contains more or less turbid serum; some soft, friable lymph is deposited on the peritoneal surface, particularly in the pelvis, with more or less injection of the peritoneum or the omentum. The uterus is large; when cut into, the tissues are healthy, the inner surface covered by a muco-purulent, somewhat reddish secretion; more or less pus-like fluid is found in the uterine sinuses, which are pervious throughout to fluid injected into the pelvic veins. What is the origin and nature of an illness such as this? A great variety of names have been applied to this condition, according to the view which authors have taken of its nature. It has been called peritonitis, puerperal peritonitis, peritoneal inflammation, metro-peritonitis, &c., under the belief that the effusion of turbid serum in the peritoneal cavity, the deposit of soft, friable lymph on the surface, and some injection of or under the peritoneum, were unquestionable signs of previous inflammatory action. But these morbid signs differ much from the appearances of undoubted inflammation of the peritoneum, and are now recognised as exudations which result from the impregnation of the general circulation with some noxious fluid or material. It has been termed phlebitis, uterine phlebitis, suppurative phlebitis, in consequence of the pus-like fluid found in the uterine sinuses being considered unquestionable evidence of the previous existence of inflammation in these canals. Dr. Robert Lee has recorded several similar cases under the name of uterine phlebitis, and has described the pus-like fluid as suppuration resulting from previous inflammation; but it is extremely doubtful whether inflammation can ever take place in the uterine sinuses. These canals are only channels formed in the contractile tissue itself, and lined by a delicate and apparently non-vascular membrane. It cannot be supposed that inflammation could occur in this delicate membrane; and if it occurred in the adjoining tissue it would be inflammation of the contractile tissue of the uterus itself. There has been considerable difference of opinion expressed as to whether the pus-like fluid found in these canals was the result of inflammatory action, or had been taken up from without through the open orifices of these vessels at the inner surface of the uterus. But this question has been definitely decided by the injection of the perchloride of iron into the gravid uterus to arrest post-partum hæmorrhage. Where death has followed in these cases the uterine sinuses have been found gorged with black grumous fluid containing an abundance of iron, and as this iron could not be formed by any secretion from these canals, it follows that it must have been taken up from the inner surface of the uterus where it had been deposited after injection. Cases similar to the one sketched have also been described as puerperal fever, the typhoid form of puerperal fever, low typhoid pneumonia, typhus, &c., when the symptoms presented during life have alone been taken into consideration. They have also been termed pyæmia, septicæmia, ichoræmia, &c., from the symptoms and course of the illness being evidently similar to those which follow the introduction of noxious fluids into the general circulation. It is to be regretted that so much confusion has been introduced respecting the meaning of these terms; but so far as the present subject is concerned, it does not appear to be of much consequence which term is employed. Mr. Spencer Wells, in the opening address, says: "Supposing that the blood in the uterine veins clots, softens, breaks up, is the seat of chemical and vital changes, is detained in or near the pelvis, or is carried away to distant parts, or alters the composition and properties of all the blood in the body; that we have purulent infection or pyæmia, putrid infection or septicæmia; can all this arise in a healthy woman placed in favourable conditions if she be not exposed to some morbid poison?" Now the first thing essential to such changes must be the presence of clots in the uterine veins or sinuses, and as these clots have never yet been shown to exist, it is difficult to see how they could be the cause of so much that is supposed to follow. I am aware much has been said respecting the formation of clots in the uterine sinuses after parturition, and that these clots mainly contribute, in many cases, in arresting any escape of blood; but I am also aware that the blood during hæmorrhage does not come from these sinuses, that it is not a venous hæmorrhage by retrogression, and that these clots, about which so much has been said and repeated, have never been shown to be present in the canals themselves. Much, I am also aware, has been echoed from one writer to another, as to the influence of hæmorrhage in predisposing the system to those conditions known as pyæmia or septicæmia; but the only relation between uterine hæmorrhage and septicæmia is one of sequence of events. Want of contraction of the uterine tissues allows the blood to escape from the utero-placental arteries; the same want of contraction leaves the canals of the sinuses pervious, allows noxious fluids to be taken up through their open orifices, and to be conveyed into the general circulation. These facts appear to be the answer to Mr. Spencer Wells's question, Can all the consequences which he has depicted arise in a healthy woman, placed in favourable conditions, if she be not exposed to some morbid poison? There cannot be a doubt that they can arise, have arisen, and will again arise under the conditions named; indeed, it has always appeared to me one of the extraordinary circumstances in relation to this subject that such questions should ever have been entertained, for everyone knows that isolated cases of the most serious affections, ending in the death of the individual, every now and then occur in all parts of the country as well as in large towns, with ladies in good health, placed in the most favourable conditions and surrounded by every care and attention that art can devise. If the succession of these cases occurring year after year be not sufficient to answer this question, I know not what evidence can be required. The same succession of cases appears to be an undeniable answer to the supposed influence of a vitiated atmosphere, of overcrowding in any institution, or the supposed benefits to be derived from cottage hospital isolation, &c. All that is required for the production of these serious conditions of the system is a means by which these noxious fluids can be readily conveyed into the general circulation, and this means exists when the uterus remains imperfectly contracted, or afterwards becomes partially relaxed, so that the canals of the uterine sinuses continue pervious, and any fluids formed at the inner surface, or which may have been injected into the uterine cavity, may enter at the open orifices of these canals, and be conveyed into the general circulation. This want of contraction, or subsequent relaxation, which practically is the same thing, may occur in the most healthy individual, living in the most healthy situation, and separated from actual or supposed injurious influences, whilst the simple means to avoid the whole of these evil consequences consists in procuring and maintaining such an amount of contraction as will render these canals impervious and prevent the passage of any fluids along them. When the want of contraction or the subsequent relaxation is considerable, a portion of the placenta is often retained, or coagula form in the cavity of the body from the blood which has flowed from the pervious arteries. In these cases the sinuses also remain patent, and the usual noxious fluids—rendered more injurious by the decomposition of the retained placenta or coagula—are taken up in larger quantity, when the symptoms become more marked and the course more quickly fatal. Whilst dwelling upon this cause of the serious condition of the general system, arising from the uterine organs after parturition or abortion, and which I am under the impression has been much overlooked, I do not wish to infer that it is the only cause, or that other causes may not induce similar results. Severe laceration of any of the parts concerned in childbirth, followed by inflammation—inflammation arising from long-continued pressure of the head forced into the pelvis,—the formation of abscesses in the cellular tissue outside the vagina or in the pelvis, and other accidents, may, any of them, produce the condition of septicæmia; but, except in rare and exceptional cases, I cannot think that slight lacerations are followed by such serious consequences as have been attributed to them. Laceration of the perineum may exist at the same time as want of contraction in the uterus, but it is the want of contraction in the uterus which admits the septicæmic condition of the system to be induced, not the laceration of the perineum. Once the way is opened to the system being impregnated with noxious fluids or materials, the effect which is produced greatly depends—(1) upon the nature of the fluids introduced, some being followed by no perceptible influence, others by serious and fatal consequences; (2) upon the amount, as in the experiments upon animals—a small amount producing disturbances from which the animal recovers, whilst a large amount always causes death; (3) the state of health of the individual at the time of impregnation—for what to one appears a poisonous dose, to another causes only general disturbance; (4) the continual renewal of the infecting matters. As Cruveilhier observed, the chief cause of the fatal result was that the purulent infection was incessantly renewed from the original source. Moreover, purulent infections have not the same decided course of action as the poisons, whatever these may be, which originate any of the infective fevers or acute specific diseases. And when we take into consideration the serious factors of disease which have been glanced at, combining together in very varying proportions in women recently confined, it is not difficult to perceive that we may often meet with combinations which puzzle our powers of diagnosis, and render it impossible for us to determine the exact nature of the illness. But because we are unable to unravel some of these puzzles, or to determine the precise nature of any complicated or obscure illness, is that any reason why we should rush into the regions of romance, or by concocting some high-sounding word or words imagine we have solved a substantial difficulty, or have explained a pathological entity? The question of contagion has been made the starting-point from which many have endeavoured to maintain the existence of a special and essential disease occurring in connexion with childbirth; but it would be impossible to enter upon this question at present. Some of the acute specific diseases, after being conveyed into the lying-in hospitals, have spread from patient to patient, and have thus been mistaken for an apparent epidemic; but the reliable evidence is not sufficient to show that any other disease than these infective fevers or acute specific diseases has been propagated, either epidemically or by contagion. Most if not all of the recorded histories on this point appear to admit of another explanation, and many to have their foundation in the management of the woman during the period of parturition, or in the circumstance that some minute yet essential particulars in the history of each case have been overlooked in the course of the illness. To quote the words of Dr. Fleetwood Churchill, "I rather think these [accounts] prove too much, for *post hoc* is not always *propter hoc*"; and, so far as bacteria are concerned, these bodies, we are told, are found in the interior of the organs in every dead body, from whatever cause the death may have arisen, their development being only a question of time and temperature.

Dr. W. T. Greene.—Assuming that the object of the present discussion is to clear up what has hitherto been confused and doubtful in post-partum pathology and therapeutics by a comparison of the records of individual experience, and not to establish any particular theory, I trust I may not be thought too presumptuous for desiring to bring before you and the Society the result of some ten years' observations extending over nearly two thousand cases, of which a proportion of about 10 per cent. suffered in a greater or lesser degree from one or other of the various affections to which parturient women are peculiarly liable, and which have so frequently been confounded together under the general name of puerperal fever—a disease of which I had for some time doubted the existence, but which I am now satisfied has yet to be differentiated as a malady *per se*. So far from post-partum febrile affections being identical, I have observed that they invariably assume one of three distinct forms, differing essentially in their origin, progress, duration, and gravity; in other words, the exciting cause may be local and transitory, local and persistent, or altogether extraneous. In the first two forms the disease may be, and often is, autogenetic, but in the third this is necessarily impossible. Firstly, very alarming symptoms may be excited by the presence of a decomposing clot in the uterus or even in the vagina, or by an overloaded state of the bowels, but yield rapidly to an aperient or the use of the syringe; and I may be permitted to observe it is unpardonable in an accoucheur who fails to have recourse to such simple remedial measures on, or even before, the first appearance of the enemy. Some time since one of my patients on the fourth day after a comfortable delivery had rigors, and when I saw her had a pinched, suffering expression of countenance, considerable abdominal tenderness, suppression of the lochia, recession of the mammary secretion, high temperature (104°), rapid pulse (130), and in fact all the symptoms of so-called puerperal fever; but she also, as I was informed by the nurse, had begun to suffer from diarrhœa, which, on investigation, turned out to be the ineffectual efforts of nature to relieve the loaded intestines. I at once washed out the vagina, as there was rather more odour present than was usual, with a diluted solution of chloride of lime, my favourite antiseptic, and ordered five grains of calomel. Next morning, though informed by the nurse that she was weak and sinking, I found my patient wonderfully improved in every respect, but very angry with me because the powder I had prescribed had, as she said, purged her instead of stopping her diarrhœa, which, however, had then ceased to be troublesome. I ordered nourishment and a due proportion of stimulants, and she made an excellent recovery; whereas had I acceded to her wishes and checked, instead of promoted, the alvine discharge, she would, in all probability, have died; for I have, I believe, in one or two instances seen a patient lost because the attendant had an unreasonable dread of cathartics. Secondly, a foul, ill-ventilated, crowded, or over-heated room, by promoting putrefaction of the lochial discharges, will often give rise to septicæmia, and, unless the cause can be removed, to death, which the most earnest efforts on the part of the medical attendant will, in such a case be utterly powerless to obviate; or hysteritis, rapidly involving the adjacent parts, may result from injury to the uterus, by long-continued pressure of the fœtal head in tedious labours, by the unskilful or incautious use of instruments, or by the well-meant but frightfully injudicious attempts of the accoucheur to pass the swollen lips of the os uteri above the head of the child during the continuance of a pain—a very common practice, and often, I am convinced, productive of extremely disastrous consequences. A primipara, aged thirty-three, who had suffered a good deal throughout her pregnancy from sickness and general debility, was delivered naturally after a favourable labour of a healthy living child, and progressed fairly for the first couple of days. She was nursed by her mother-in-law, who persisted in keeping the room at stove heat. On the third day the patient had rigors, and severe symptoms soon set in, but subsided on the arrival of a more intelligent nurse. Unfortunately this person was soon called away; the mother-in-law became once more in the ascendant, stove heat was renewed, all my orders disregarded, and the patient died on the tenth day after her confinement, with every symptom of blood-poisoning. I might multiply instances, but *cui bono? Ab uno disce omnes.* In every such case—that is, ending in the death of the patient—I have no doubt (and this constitutes the essential difference between what I may call the first and second forms of post-partum febrile affections) careful inquiry would elicit the fact that the woman's health had been for some time in a more or less unsatisfactory condition, and to that cause, rather than to any accidental lesion, the unfavourable ending of the case must be ascribed; just as we not unfrequently find in the other sex, where the health has not been all that could have been desired, the most trivial injuries giving rise to septicæmia and death; otherwise nine-tenths of all women must sink after their confinements. In the third form, if I may so term it, of post-partum fevers, which comprises at least six-eighths of all cases, the contagion is conveyed to the patient from without, in shape of the germs of one or other of the zymotic class of diseases, by the medium of some one—doctor, nurse, or friend—recently in attendance on a person suffering from the same complaint; and of this fact I have had positive proof, although the possibility of its occurrence has been denied, and it has been even attempted to be proved that because some women resist the contagion none can suffer by it—a mode of reasoning, however, undeserving of further notice. Of all the exanthemata, scarlatina, in my experience, most frequently attacks the parturient female, and though giving rise to very alarming symptoms, is happily rarely fatal. Some years ago, during the earlier part of my professional career, I was attending a lad with scarlatina anginosa of a severe type, and at the same time nearly all my puerperal cases exhibited febrile symptoms and had more or less sore-throat, although the characteristic rash did not in every instance make its appearance. Several of the children sickened as the mothers were recovering, and exhibited every feature of scarlet fever. Fortunately none of them—parents or children—died, but I received a lesson I shall not soon forget. Since then, at different times, I have met with other similar cases, and have always been able to trace the contagion to its source. Post-partum small-pox I have met with in two instances where the preliminary symptoms were identical with those usually ascribed to puerperal fever. In both of these the patients recovered. Of post-partum measles I have had no experience, but I have met with several cases of erysipelas occurring in recently-confined women, who all succumbed to the disease. In one of these cases I was able positively to trace the disorder to its source. The nurse had come straight from the bedside of a man suffering from phlegmonous erysipelas, of which he afterwards died, to attend upon my unfortunate patient, in the raw placental surface of whose womb the insidious disease found too ready a nidus, and thence spread rapidly to all the adjacent parts, terminating fatally on the tenth day after the poor woman's confinement. The infant also died of the same complaint, thus confirming the diagnosis in the mother's case. I have had one case of post-partum typhoid fever, occurring soon after delivery in consequence of the patient inhaling the noxious emanations of a drain under the window of the breakfast-room in which she had been confined. After a hard struggle for her life this woman recovered, but her infant died with every symptom of typhoid fever. If it be asked why scarlet fever &c. assume so formidable a character in parturient women, I reply that in them the absorbents are in the highest state of activity, and the poison in consequence is conveyed with extreme rapidity to all parts of the system, and produces a correspondingly grave effect. With regard to the animalculæ which by some are supposed to play so important and destructive a part in septicæmia generally, and notably in the case of parturient women, and by others to be a delusion and a snare, I cannot boast of any great experience, but I can imagine that their presence within the body would have a tendency to cause increased irritation, just as maggots in an open wound would certainly retard if not prevent its closing. Hence the value of antiseptic lotions, especially the chlorides, which are fatal to bacteria and their congeners. To sum up, there is no such disorder as puerperal fever, and therefore the erasure of the term from the nomenclature of diseases is very urgently demanded, as utterly misleading, and in lieu thereof might be advantageously substituted the name of the complaint from which the patient had suffered, with the qualifying epithet "post-partum," thus:—Post-partum septicæmia, post-partum scarlatina, erysipelas, &c.; and a little care in analysing the symptoms and the history of each case would almost always render the diagnosis absolutely certain.

Dr. Routh.—I am anxious to make a few remarks in this discussion, since in early life it occurred to me to have seen perhaps a greater number of cases than any person in this room, having been present during part of that terrible epidemic which took place in 1846 and part of 1847 at the Vienna Hospital. During the first of those years 456 women died of the disease, and in the second 176. The greater number of those cases I saw, and therefore I had an opportunity of studying the disease very closely. On my return to England I published a paper, which is extant, and is probably known to many members present, therefore I shall only refer to it, in which I showed that the disease was communicated directly by inoculation from the hands of the medical students who came from the Coroner's Court, and, satisfying themselves with simply washing their hands in a little water, made examinations of women about to be delivered. One point in regard to the disease was clearly brought out

—namely, that it was not contagious from one person to another. That fact I took a great deal of trouble to find out, and I think it was proved in the most satisfactory manner that the disease was not communicable from one person to another, except the discharges were in some manner communicated, or except in the case of examinations made by the students under the circumstances I have mentioned. Many of the nurses and midwives who attended those patients were married women, and many of them had children, but not one of those women caught the disease. In the division where the labours were attended by women who had nothing to do with dead bodies, the disease did not exist, or if it existed at all the cases were so few and far between that there was no belief that it could be produced in any way by the attendants. And after the plan had been adopted of compelling every student to wash his hands in a solution of chloride of lime before he attended a midwifery case, the mortality in the first division, where about 3500 women were annually confined, diminished exactly to the same figure as in the second division, where a similar number of women were attended by midwives only. Well, that disease I showed from the evidence was not contagious from one person to another. That is exactly what is true of surgical fever. We all know that very often we communicate a disease to a lying-in woman if we come from a case with our fingers contaminated by some discharge. The records of medicine abound in cases of the sort. The cases published by Dr. Storr some years ago in the Transactions of the Provincial Medical Association showed how often the disease was produced in that way. Therefore I say it is clear from the evidence at Vienna upon a large scale, and from what I have seen and read upon a smaller scale in my own practice and that of others, that one variety of puerperal fever can be and often is communicated by direct inoculation of the practitioner. In the case of the fever at Vienna the children died generally a little before the mothers, and in all those cases it was found that peritonitis existed in the child. In Dr. Storr's cases it was found that many of the husbands of these women contracted peritonitis; and we have heard to-night of some cases in which the disease communicated was erysipelas. Therefore we must admit that under certain circumstances there is some contamination that takes place between parties coming in close contact, probably analogous to that which takes place with typhoid fever, which may be said to be communicated by discharges or by the powerful odour emanating from the patient. No man can read all the literature upon the subject, I think, without being convinced that there in another variety of puerperal fever which is eminently contagious. Whether it be communicated from erysipelas direct, or from typhoid, or from any of these diseases, it is communicable from woman to woman, even from woman to man. There is, I think, a point in which we have not made a clear distinction. There is indubitably a peculiar point in the contagion of several different fevers at which, when it attacks a lying-in woman, will develop in her a particular disease, call it puerperal fever, or call it a modification of the disease which originally infected her, but which, applied to another woman, would extend, and thus produce an epidemic. If we look at that question on a broad basis, we must come to the conclusion that some cases are not contagious and some are, and that those that are contagious are communicated by infection from other cases.

Dr. GREENE.—I may mention a fact which I omitted to state, that a midwife, whose son was suffering from erysipelas, communicated puerperal fever, or some febrile affection, which undoubtedly was erysipelas, to a number of her patients, many of whom died. That occurred recently.

Mr. WALLACE.—I am pleased to hear what Dr. Routh has said about the contagiousness or non-contagiousness of some cases of puerperal fever. Up to last October I was in the happy position of having attended over two thousand cases without having lost a woman from any disease whatever; like some of those gentlemen who write to the papers and say they have attended so many cases without a single death, and therefore think they are never to have one. However, my turn came at last. My *locum tenens* attended a primipara on October 5th. The house was in a bad hygienic condition, the rooms being ill-ventilated and most offensive, and the drains smelling. The woman died after six days of what I should call typhoid fever modified by the puerperal condition. The most singular part of the case was this. I should explain that I came back from the country the very night the woman was confined, and I attended her afterwards myself. During the first two days after my return I attended four women in their confinement, and they all did badly; none of them died, but they were all more or less ill for some time, and two or three of them barely escaped with their lives, so much so that I was compelled to give up midwifery practice for three weeks, when my trouble ceased. About two months afterwards a medical friend of mine attended a case for me, in which the woman died after five days of metro-peritonitis. While this woman was ill I attended several cases, and they none of them exhibited any bad symptoms whatever. I continued to attend midwifery cases, and all my cases did well; but after two months there was another case where the woman died. I may mention that in the second case the woman had a dead child, and there was decomposition of a portion of the placenta. What I wish especially to say is, that what would be called the pyæmic cases were non-contagious. I may also state that during 1870 in my neighbourhood there was an epidemic of scarlet fever. I had many cases to attend, and I also had a good deal of midwifery, but none of the women were taken ill. On several occasions children with the rash out were in bed with the mothers when they were confined. The same has been the case with measles. During the epidemic of small-pox which occurred in my neighbourhood in the East-end of London in 1871 those puerperal women who took small-pox had small-pox simply, not at all modified by the puerperal condition.

Dr. GRIFFITHS.—In the discussions which have preceded to-night's there seems to be some discrepancy as regards the relation of scarlet to the so-called puerperal fever, which, with the greatest diffidence, I submit may be explained in the following way:—Some gentlemen have seen and described true scarlet fever running the regular course, the subject of it happening, in the chapter of accidents, as it might be said, to be the lying-in woman in whom that fever which we know by the name of puerperal fever was not induced. Other gentlemen have seen after labour symptoms which they have considered scarlatina, but which really do not constitute that affection, being simply the outward and visible signs of the inward autogenetic poison of which—as, indeed, the word "autogenetic" implies—the woman is herself the factor and subsequently the recipient—recipient not alone because the poison generated in utero lies in or is received by the uterus, but because it is received into the lymphatics, the veins, the peritoneum, and into the body generally, as described by Dr. Tilt in his paper on lymphangitis in Pelvic Pathology, in the 16th volume of our Transactions, and alluded to by him in his recent speech. With the train of symptoms to which I refer, and which has been termed scarlet fever, who practising obstetrics has not had experience of it in cases of what, for the sake of distinction, we must term puerperal fever? But, Sir, is it scarlet fever at all, at least that form contracted from another affected with the ailment, and which in the usually accepted meaning of the name constitutes the true disease? The conditions alluded to, and which are identical with scarlatina, nay more, are in some instances, perhaps, the same, are the result of pyrexial action, the indication of latent mischief, and have their origin not from scarlet fever contagion—that is, from a scarlatina-infected person, the woman never having been exposed to the scarlatina virus,—but from the presence of some putrid or offending matter in uterus or vagina. The sickness, the headache, the hot pungent skin, the sore-throat and rash, congested eyeballs, the jaundice, the delirium, the oppressed heart and breathing, and, later, the diarrhœa; these are not scarlatina, in the usually accepted sense of the word, but a group of symptoms pointing to the toxæmic condition of blood dependent not upon the entrance of a specific virus, but simply of the noxious elements resulting from putrescent animal matter—are, in fact, the sequelæ and manifestations of the blood-poisoning which occasions what is termed puerperal fever, and which, if not checked or corrected, would immediately end fatally. In a scarlet fever epidemic, such happening to a lying-in patient would be set down to the scarlet fever poison; but I have seen them where no scarlet fever at all existed, and where no exposure to it had taken place. Those gentlemen who have seen scarlet fever attacking the lying-in, and running its usual course, well-defined, without inducing any form of puerperal fever, would do good by relating whether the lochia were offensive before the scarlatina set in, or at any time during its progress. If not before the invasion of the fever, then I say the case is one of true scarlet fever; but if the discharge become offensive only in the course of the scarlet fever, I would submit that the fever poison, perverting, as we all know it does, the entire blood, has vitiated, and it may be even rendered putrescent, the outcome of the blood—I mean the lochia; the relation of the scarlet fever being to the offensive discharge as cause to effect, the reverse of that which obtained when the symptoms exist which I have demonstrated as being those of so-called puerperal fever, and to which we might apply the term bastard, or simulating scarlet fever. Those gentlemen who hold that scarlatina is a great agent in producing puerperal fever would do well to tell us whether the scarlet fever symptoms came on before labour. If not, on what day after delivery? They should also state whether the lochia were fetid. If they were, how many days previous to the scarlet fever symptoms had they been so? I am led to the conclusions I offer by a case of autogenetic poisoning at this moment under my care, in which most, if not, indeed, all the symptoms of scarlatina obtained, but which, recognising to be wholly the consequence of a morbid condition of the uterine system and its excretions, the lochia, I attacked by imitating the eliminative action of involution, grasping the soft, spongy, uncontracted uterus with my hands, compressing it and expelling some clots, washing out the putrid or putrescent discharges of the womb and vagina by means of Higginson's syringe, Condy's fluid and warm water being used every two hours till the lochia became quite inodorous. Had I, however, seen the patient for the first time when those apparently scarlatinal symptoms were well developed, I might have erred in supposing I had a case of scarlet fever to deal with, have treated it as such, and lost my patient; but being alive to the puerperal facts to which I have drawn attention, I at once proceeded as I have described, and the correctness of the diagnosis was evinced by the immediate improvement in my patient, commencing as it did from the very time I got rid of the offensive clots and washed away the foul lochia. All the group of evils in this case might be termed scarlet fever, yet all at once disappearing under the defouling treatment named showed incontestably that the diagnosis was correct. Moreover, since her recovery I have made inquiries, and find no exposure to scarlet fever nor any presence of it in the town. One difference I noticed: there was no desquamation of the skin, although I should not have been surprised had such taken place, so high did the temperature run. I admit—as Dr. Savage, I think, said—there may be cases of septicæmia running to a rapidly fatal issue without any of the pyrexial disturbances I have named, or even any elevation of temperature from first to last; but that is where the patient is stricken down and overwhelmed by the dose of poison, or where the febrile symptoms occur in our absence, and hence may escape the observation of even the astutest. The same remarks will hold good of the rash as adduced by Dr. B. Hicks. I am led up to these conclusions because lately my mind has been exercised upon what I consider to be a fact—namely, that scarlet fever and typhoid may originate in the same way, from the same infecting source of poison developed in different persons or in the same persons at different times and under different circumstances; the poison at one time, determining to the lymphatics and glandular systems, producing what we know as scarlet fever, at another time determining with greater virulence to the intestines, particularly Peyer's patches, as in typhoid fever. In this—although I had arrived at my goal without knowing the way to it had been trodden before me—I find I am borne out by the previous researches of Dr. John Harley, which he published in a pamphlet he has had the kindness to send me since I commenced my investigations, also by the researches of Dr. Tilt, made known to us in his paper on Lymphangitis in "Pelvic Pathology," by Dr. Tilt's speech, by the speeches of those who have preceded him, and by my own at present somewhat crude experience, which I value very slightly indeed till I verify and check it by further careful inquiry. Bearing in mind, therefore, the life symptoms which exist in scarlet fever, puerperal fever, and typhoid, also the pathological conditions found after death, and how closely allied they are—nay, more, how much alike in a number of instances,—we can see how readily the first—that is, scarlet fever—can run into the second, puerperal fever; the second into the third; how typhoid came to be supposed to originate puerperal fever (Sir Henry Marsh's opinion, as quoted by Dr. Squire); and how true so-called puerperal fever may clothe itself in the garments of scarlet fever, so that only with difficulty it can be distinguished.

Mr. SPENCER WELLS.—The great difficulty I have in replying to-night in the few minutes that remain before the end of the discussion, consists principally in the great number of speeches that have been made, and the extremely numerous and important topics which have been suggested by different speakers. But I think I may congratulate the Society upon the very great importance of the discussion that has been carried on, and upon the very great ability which has been shown by a great number of gentlemen who have addressed us, and by none more so than by our friend from the other side of the Atlantic, to whom we have all listened with so much pleasure and instruction to-night. I will, with your permission, while what our friend has said is fresh in our minds, refer to two or three topics which he has raised, inasmuch as that will perhaps prevent the necessity of a good deal of repetition in discussing the first three questions which were placed before the Society in the little programme by which I endeavoured to give a direction to the thoughts of gentlemen who were going to speak. There was really nothing in these questions intended in the way that Dr. Farre supposed to lead to any very definite conclusion, or to any kind of suggestion that I myself had formed any decided or positive opinion upon them; it was more with the hope that different gentlemen would take up the different questions according as their opportunities gave them means of information, and would bring before us the results of their own individual experience upon these different questions. Dr. Barker has at once started the question by his statement that we must, as he says, from the identity of cause presume identity of result, or at any rate that if we have a specific morbid poison to deal with, that specific morbid poison always produces the same results; or, as I think I understood him to say, that I might, from the same specific morbid poison get very different results in different women under different conditions. For instance, given a morbid poison and that morbid poison received by a healthy woman, it would produce in her a very different condition from what it would produce if received by a puerperal woman, and by the puerperal woman if she is in an unhealthy condition at the time. I do not know that I exactly interpreted his meaning, but if I did I should like to say that I would go somewhat beyond that, and assert that if you have a specific morbid poison it must, under all conditions, produce identity of results. I do not believe if you inoculate small-pox in a patient that you can produce a chancre; I do not believe if you inoculate a chancre in a patient that you can produce hydrophobia; I believe you can certainly produce identity of result from identity of cause in the animal body as you do in the vegetable. If you sow a grain at the proper season in a fruitful soil the seed will germinate; if you sow a grain of wheat you do not get barley or oats. The seed germinates, and you get the same variety of vegetable produce. It is the same, I believe, with animal poisons. If you sow a seed of hydrophobia, or a seed of syphilis, or a seed of small-pox, in a patient, you get a crop of small-pox, a crop of syphilis, a crop of vaccine, or a crop of erysipelas, according to the poison you have sown. It is the same with medicine; if you give a dose of castor oil, you do not send the patient to sleep; if you give a dose of opium, you do not produce purging. All these poisons produce the same result. So with puerperal fever; if you suppose that in puerperal fever you have a specific disease different from any other fever, or from any other condition which we meet in surgical or medical practice, you must show us some cause which will, under all conditions, produce the disease just as certainly as you produce small-pox by inoculating small-pox, or scarlatina by exposing a patient to poison of scarlatina. That carries me to the question which Dr. West started, as to what share bacteria or some other form of vegetable or animal life in its lowest form may have in producing these diseases, or carrying the poisons to produce them. I agree with Dr. West that we are only on the threshold of this inquiry, and the question which I put before the Society was simply what relation have bacteria and allied organic forms to the pyæmic process in the puerperal state, in other words, to puerperal fever? I put that question in hopes that Dr. Burdon-Sanderson, or some other gentlemen who have lately made such important investigations on this subject, who have investigated the subject of splenic fever, sheep-pox, relapsing fever, diphtheria, and erysipelas, would have come here and given us the benefit of their experience. The great use of this discussion has been that it has brought here, not only the ordinary fellows of the Society, but others from distant parts—a professor from Glasgow (whose candour and ability excited universal admiration amongst us, and a hope that some day he may occupy a still more important post than that which he now fills so creditably), some of our past presidents, several of our honorary fellows, gentlemen from the provinces practising obstetrics very largely. It has also brought a distinguished physiologist, who is among us to-night, and who I was in hopes would have spoken, who has done more perhaps to prevent disease in the country than any other man—Dr. William Farr; who, by making known the incidence of diseases and showing their causes, has done more perhaps to check preventable disease than anyone else. I hope that at some future time he will favour the Society with some statistical account of the prevalence of this fever in different localities. We have been favoured by a promise from Dr. Farr of another paper on the subject, so that, at any rate, the discussion has not been fruitless in good to the Society, and I trust that it will be beneficial to the profession at large. We have also been favoured by Dr. Farr with an account of a recent epidemic of puerperal fever in a district in the south of London. It is only for the week ending the 19th of June. In the printed returns of deaths it was stated that the cause of death was given as peritonitis and fever, which were presumably cases of childbed fever. There were three cases in the week and one in the preceding week, which, it was found on investigation, were all attended by one medical man. Between the first case and the other three he attended two cases without a fatal result, so that the first case was probably the cause. It has not yet been quite ascertained how the first case began—whether it was a case of ordinary peritonitis or not. The investigation is still being carried on. Scarlatina is still prevalent in the district. In the same week there were nine or ten deaths registered. An interesting question arises, and is being investigated, whether the two women who escaped from childbed fever between the first and third cases by this gentleman were protected by previous attacks of scarlatina. That is a most important matter. It is still being investigated, and I hope Dr. Farr will let us know the results. I have one or two letters here showing the very close connexion of scarlatina with puerperal fever, which it will, perhaps, be interesting to the Society to read. One is from Dr. Jackson, of Notting-hill. He gives the particulars of a case that occurred in September, 1864. The husband, about thirty, had a severe attack of scarlet fever, from which he recovered. The wife, who had some years previously had the fever, and who was in the end of her eighth month of pregnancy, waited upon and attended her husband day and night. In about fourteen days from the date of her husband's illness she began to feel ill, shivering and feverish, but had neither sore-throat nor eruption. Labour suddenly and sharply set in. The child was born alive, well developed and strong, but covered with the distinct and characteristic scarlatina rash. From birth it was restless and uneasy, and died on the third day. The mother progressed most satisfactorily, and the feverish symptoms abated. Milk and lochia were well established. Some slight apparently dyspeptic symptoms were complained of at the end of a fortnight, but these gradually disappeared. The cuticle on both hands desquamated, and at the end of the fifth week she was quite well, and left town for the country." I have several other letters giving instances of the close connexion which Dr. Barker has alluded to between erysipelas and puerperal fever. One is a letter from Mr. Freer, of Stourbridge:—"Some years since I left home for a few days' holiday, leaving two patients expecting their confinements. The evening before I started my father was thrown from his horse upon the front and right olecranon. The next morning the arm was red and swollen. Two days afterwards he attended both my patients, who had easy, natural labours, not requiring any assistance, and my father was not half an hour with either of them. Upon my return on the fifth day I found both my patients dying, and my father's arm so much inflamed that I had to make incisions from the elbow to the wrist. Each case had rigors in twenty-four hours. Ten years since I was engaged to attend the wife of a clergyman in her first confinement. She was a very fine, healthy lady, aged twenty-six. Upon entering the bedroom I found a nurse in attendance with an erysipelatous blush and swelling upon the side of the face. Upon inquiry she told me that two days before she had been in a Liverpool hospital to have the nasal duct opened. My patient was seized with rigors at the end of thirty hours, and died of puerperal fever on the eighth day. The nurse died of rapid erysipelas of the head and neck on the twelfth day." I have also a letter from Mr. Pemberton, of Banbury, which I need not read through. It goes to show that in a house where there is typhoid fever a woman being confined may get puerperal fever, but then I do not think at all that it follows from that that the cause was the same; for you may from drains get a variety of poisons, a variety of chemical and organic products thrown out, and one patient may get one and another another. You may get sulphuretted hydrogen, phosphoretted hydrogen, and a variety of chemical substances, and vegetable or animal organisms of a low form, and one may affect one patient and another another. Showing how this bears upon surgical practice, and somewhat in answer to the question which Dr. Playfair started, I will read a letter from Dr. Keith, of Edinburgh, giving me an account of a most remarkable series of cases, in which erysipelas, puerperal fever, and septicæmia after ovariotomy seem to have been in close association. "On the 19th of May my friend who assists me at my operations became uneasy for the first time about a puerperal case. The patient died on the 26th. On the 24th he helped me at an ovariotomy, but did not see his puerperal patient till after the operation. Next morning my patient was in a typhoid state, and had bad bedsores, with all sorts of eruptions and superficial abscesses, and recovered after this pyæmic condition had lasted a month. There was no suppuration in the pelvis. On the 30th, he assisted me at a tedious ovariotomy. The patient was quite well for six days, the pulse and temperature natural. She then suddenly shivered, the pulse rose to 170 and the temperature to 106° within a few hours, and she died five days afterwards. On the same day he opened a small superficial abscess in a lady's neck. She went after this to the country, was quite well for five days, then shivered and died five or six days after of erysipelas of the head. On the 6th June he attended a simple case of natural labour in a healthy woman. She shivered next day, and died on the 10th of septicæmia. As he went home from this confinement he himself shivered, and was laid up with erysipelas of the face, from which he recovered. The medical man who attended the last puerperal case during the few days she lived examined for an instant a patient in the first stage of labour, four days after the death of the last case, but declined to attend her. This patient had metritis, and is now recovering, the veins of the left limb being all plugged up." I have seen this kind of thing myself in surgical practice, and this led me to be extremely careful in getting the gentleman who attends the operations at the Samaritan Hospital to sign a paper before going into the room that he has not attended an infectious case for seven days, and has not attended a post-mortem examination during that time. I believe that a precaution of this sort would really very much protect puerperal women from many of the infectious diseases to which they are subject, and which, I believe, are, as scarlet fever, or as measles, or as small-pox, or as erysipelas, confounded together under the name of puerperal fever. I hope the end of this discussion will be to give more accurate names to the different conditions which have been confounded together under that one name. I should like to say a single word as to the great question of what is called homicide by infection, and the attempt that has been made, I think unfortunately, to enlist the sympathies of this Society in the protection of careless and ignorant women who deserve the punishment they have got. I think if a woman is cautioned by her medical man, who tells her that she has attended a woman in her confinement who has died of puerperal fever, and that if she attends other women she is liable to poison them, and if she goes on in defiance of this caution to attend other women, and says, "Well, if this one dies, I will give up," such a woman is not deserving of the sympathy or help of the Society. I think we should do good service if we rather stimulated the fellows of the Society and the midwives that they employ, not to carelessness, but to additional caution, teaching them not only to wash their hands, but to use disinfectants, and above all things to avoid any possibility of doing damage to patients who employ them. Only this day I heard of a case which shows that a practitioner would do well to err on the side of over-caution. I was asking about a gentleman whom I knew some twenty years ago, who had settled down in practice in a large town. He was an able man, a gentleman in every sense of the word, a person of good character and great ability. I was told that he did not get on. I asked why, and it appeared that in early life in that town he was introduced to two families. He attended a lady in one of those families, who died of puerperal fever through no fault of his; he attended another lady shortly afterwards, and people blamed him and said that, having attended one woman with puerperal fever he ought not to have attended the second, and he never got over it. I will not say that he deserved his fate, but certainly if he had shown a little more caution, he would have proved the truth of the old maxim that "honesty is the best policy." I believe the fellows of the Society will do great good not only to themselves but to all whom they influence if they inculcate, not carelessness, not the protection of ignorant midwives, but instruction to those midwives that they must be over-cautious, and that if they find themselves in danger of propagating or carrying about disease, they must err on the safe side and say, "For a time I will give up practice. I will not run the risk of damaging the patient who has entrusted her life to my care."

SANITARY NOTES AND REPORTS.

THE second annual report of Dr. Alfred Hill, medical officer of health and analyst for Birmingham, has recently been issued, the chief feature of which relates to the epidemic of small-pox, from which the town has been suffering since the winter of 1871. During the past year it occupied the second place in the order of fatality, 637 deaths having occurred out of 3791 cases, 3367 of which are described as vaccinated, 396, or 10·45 per cent., not vaccinated, and 28 doubtful cases. So that the death-rate was 176·5 per 100,000 of the population, had since 1873 increased fivefold, and was of course enormously higher than that of any other town in the kingdom. The analyses of well-waters show much contamination with sewage-matters of excrementitious origin, derived from drains, middens, cesspools, and surface-filth; and Dr. Hill reports also, as regards the waterworks water, that the "organic impurities are much too high, and very probably productive of diarrhœa." A borough hospital was commenced some eight months ago, and the buildings have recently been increased so as to provide two distinct wards for the treatment of scarlet fever. As regards sewage and refuse disposal, it appears that there are in the borough 190 miles of streets, only about 130 miles of sewers, and four miles of paving. Indeed, it would seem, from the summary of information given in the report, that Birmingham is even more behindhand as to sanitary matters than is generally supposed, and, as we take it, no place in the kingdom more requires the services of an able and energetic health officer. Dr. Hill has included in his useful report a large array of well-tabulated statistics and some simple formulæ of advice on the prevention and management of scarlet fever.

Dr. C. E. Saunders, health officer for the combined districts of Middlesex and Herts, exercises sanitary control over a considerable extent of country, forming, as he reports, "a compact right-angled triangle, the sides of which measure twenty-one, twenty-four, and thirty miles respectively," including a total area of 150,585 acres, and a population of 108,120 persons. The report is very ably prefaced by a summarised description of the geology and natural drainage of the district and the chief industries of the inhabitants. The water-supply and disposal of sewage are then attacked, and the author gives to each and every authority for whom he works a brief account of the year's labour, with a table of mortality returns, and a list of the nuisances dealt with in each district. There is nothing in the report that calls for special comment, but its plan of arrangement is commendable, and worthy of imitation by the few who have charge of large combined and, as we should think, unmanageable districts.

Reports of the condition of Rotherham Urban and Spilsby Rural districts are before us. The former, compiled by Dr. Junius Hardwicke, describes the geography and geology of the district, present water-supply, &c., and concludes with some very diffuse recommendations, among which we find the following:—"9th. That a heavy fine be inflicted on those who are found throwing excrement or other filth into the streets." From this and other notes we infer that Rotherham somewhat needs sanitary supervision.

Dr. West Walker, health officer of the Spilsby district, ambitiously endeavours "to account for every death which has occurred in the district during the past year," and gives a fairly popular description of the sanitary condition of his district, which is essentially rural, the population being employed almost exclusively in agriculture.

Most of these reports contain caligraphic errors, that, with ordinarily careful supervision of the authors, ought to be avoided.

THE MEDICAL COUNCIL AND THE REGISTRATION TAX.

To the Editor of THE LANCET.

SIR,—I, in common with a large number of the profession, agree with your correspondent "Non Placet" in thinking that the answer of the Medical Council to applicants for aid is sufficient to raise strong feelings of indignation in those who are taxed so heavily to keep up the Medical Council. How can it be otherwise when young men entering the profession are called upon, at a time when frequently they can least afford it, to pay the sum of £5, in return for which they receive no apparent advantage? I believe that very few compelled to pay this fine (for it is nothing less) could give any statement of the benefits that they will derive from it; and it is undoubtedly the general opinion that the Medical Council does as little work as it is possible to do, and gets a large sum of money for doing that little. What can be more unseemly than the long and wordy speeches which occupy the greater part of the sittings of the Council? and how small is the benefit that the profession at large derive from them. In the really important work of protecting the profession from the inroads of unqualified practitioners the Council does its best to maintain its policy of "masterly inactivity."

There is another point to which I have referred in a previous letter (May 3rd, 1873), and that is, the grievance of having to pay additional fees for registering additional qualifications. This is a gross injustice to those compelled to register as soon as qualified. Surely it is enough to be mulcted in so large a sum as £5, without being obliged to pay a fee for registering *each* additional qualification that may be obtained afterwards.

I have not the statistics of 1874, but in 1872 nearly 400 (397) additional fees were received, amounting to £100, and the income of the Council for that year was nearly £9000.

If the profession were to express their firm determination to obtain some benefits for this large taxation, there would assuredly be some means of obtaining it.

I am, Sir, yours truly,
LEONARD CANE, M.D. and B.S. Lond.

Peterborough, July 12th, 1875.

THE annual meeting of the friends of the Chelsea Hospital for Women was held at the London Tavern last week, under the presidency of Lord Wharncliffe. The chairman, in congratulating the meeting on the increased prosperity of the institution, as shown in the augmented funds and the larger number of patients relieved during the year, expressed the opinion that more good would result from increasing the number of out-patients than by adding to the number of in-patients.

THE LANCET.

LONDON: SATURDAY, JULY 17, 1875.

ALTHOUGH the accumulated experience of many surgeons during many years has done much to determine the respective merits of the two operative procedures—lithotomy and lithotrity—for the removal of vesical calculus, it can scarcely be said that the data we have hitherto possessed have been sufficiently numerous or unequivocal to ensure a unanimity of opinion or uniformity of action. It is true that there has been for many years a general agreement concerning the two operations among some of the leading authorities; but to many good surgeons lithotrity is, even in the present day, practically little known, while lithotomy is regarded as the only safe and legitimate mode of treating stone in the bladder. This state of things is, perhaps, only natural. Until within the last few years no reliable statistics of lithotrity existed, whereas lithotomy from the earliest times has been deemed the triumph and glory of surgery. In the statistics of lithotomy cases have been dealt with by the thousand, and very trustworthy information has been obtained respecting the relative mortality at all ages, for all kinds of stones, and for all sizes; but the statistics of lithotrity have for the most part been drawn up by friends or by foes, by whom the operation has been either unduly applauded or too severely denounced. CIVIALE, for instance, defended the procedure with all the ardour of a partisan, and did not hesitate to allege that a fatal termination after the crushing operation was almost impossible. If the patient died, the cause of death was attributed to some extraneous cause—never to the operation. This indiscriminate praise, when compared with the less favourable experience of others, could scarcely fail to produce considerable distrust in the minds of impartial observers, and for a time the operation fell into disrepute with many of the best surgeons in this country. Happily, however, the operation has been rescued, in this country at least, from both the unreasonable adulation of its advocates and the wholesale condemnation of its opponents by the honest and judicial representations of Sir BENJAMIN BRODIE, Sir WILLIAM FERGUSSON, Sir HENRY THOMPSON, and others; and may be said, at last, to have assumed its proper place in operative surgery.

It is a truth now very widely accepted, that neither lithotomy nor lithotrity is suitable for every case of stone in the bladder; but that, under certain circumstances, each has its special and peculiar advantages. The conditions that justify the performance of one or the other operation are generally readily recognisable, and there is usually very little difficulty in deciding which procedure offers in a given case the best prospect of success. Indeed, all experience has tended to show the paramount importance of ascertaining what these conditions are; for on a just appreciation of them will the ultimate results very materially depend.

Safe and efficient as lithotrity has been shown to be, it is, nevertheless, true that there are states of health and conditions of kidneys, bladder, and urethra, or of stone, that absolutely preclude it. Lithotrity is, in fact, so much an operation of election that the general results will depend more on the care and attention bestowed on the selection of the cases than on the manual dexterity of the operator; and, unless this fact be kept prominently in view, lithotrity may in the long run be made more disastrous and fatal than lithotomy.

It is not our province now to enter into all the details of the operation of lithotrity, nor even to consider all the conditions likely to ensure a successful result or those calculated to militate against it. We shall for the present base our remarks on the broad question of comparative mortality.

By an analysis of more than 1800 well-authenticated cases Sir HENRY THOMPSON showed that the average mortality of lithotomy at all ages was about 1 in 8; but that by excluding all the cases under sixteen years of age, in which the mortality was 1 in 15·5, the proportion of deaths rose to 1 in 5 for all ages beyond sixteen, the increased mortality being in direct ratio to the age of the patient. The results obtained by Sir WILLIAM FERGUSSON, and set forth in his lectures delivered at the Royal College of Surgeons in 1864 and 1865, were similar. In 110 cases in which lithotomy was performed in the adult there were 33 deaths, or 1 in 3·5.

If we now compare these results with those obtained by lithotrity, always premising that the cases have been properly selected, the advantages of the crushing operation will at once be apparent. In 115 cases, in about 100 individuals, recorded by Sir BENJAMIN BRODIE, there were 9 deaths, or about 1 in 12. In 204 cases, in 185 individuals, the mean age of whom was sixty-one, recorded by Sir H. THOMPSON up to 1870, there were 13 deaths, or about 1 in 15·5; and in the 87 cases of lithotrity recorded by Sir HENRY in our columns (April 3rd), and the subsequent progress of which we published on the 3rd inst., there were 4 deaths, or about 1 in 22, the mean age of these individuals being sixty-three years and a half. Sir W. FERGUSSON's results recorded in 1865 gave 12 deaths in 109 cases, or 1 in 9. These facts, which cannot be gainsaid, argue most convincingly in favour of lithotrity; but they should not be made to weigh unfairly against lithotomy, for which many of the worse cases, obviously unfit for the crushing operation, are reserved.

An important question respecting lithotrity still, however, remained practically unanswered—namely, the condition of patients a year or two after the accident. An impression very generally prevailed that recurrence of stone was more common after lithotrity than after lithotomy. This impression was doubtless to some extent true, but the difference in the immunity afforded by the two operations had evidently been exaggerated. We need only refer to the answer to this question published in our columns by Sir H. THOMPSON a fortnight back in confirmation of this statement. In that article not only was the average mortality shown to be lower than that of lithotomy, but a large number of persons (28 out of 45) were stated to be "in good health and active existence."

There is another point, incidentally referred to by Sir HENRY THOMPSON, which has not yet received the attention it deserves—namely, the value of the lithotrite for the removal of recurrent phosphatic calculus. It is manifestly impracticable to repeat lithotomy every time a phosphatic calculus forms; whereas by means of lithotrity these accumulations may be removed with comparative impunity several times a year. In such cases the patients are actually kept alive and well by lithotrity. Valuable as lithotrity has been and is, it may be doubted whether its full powers have yet been developed. The notion that lithotomy for the removal of stone from the adult bladder will some day be a rare if not an obsolete operation is not perhaps so utopian as we sometimes imagine. As the pathogenesis of calculus becomes more accurately worked out, as the methods of constitutional treatment become more scientific and the modes of physical examination and diagnosis more exact, it may well be that, though the formation of calculus may not be altogether prevented, the cases of stone in the bladder may all be detected while in that stage in which lithotrity has been demonstrated to give the best results.

We notice with much pleasure that the President of the General Medical Council has intimated that it may be a future duty of that body to institute inquiries into the character and extent of the various examinations in Arts which now form the portal to our profession, and we have no doubt that the result of a few visitations during these examinations will be even more valuable than those which must ensue from the visitations of the examining bodies whilst the professional examinations were in progress. The fact that a candidate for the M.D. of the University of Durham (who seems to have already had the M.A. degree of the same University conferred upon him) was quite ignorant of composition and spelling appears to have stirred up the virtuous indignation of several of the members of the Council; but we venture to suggest that this is by no means an isolated case, and that the above University is not the only sinner. We have frequently met with both students and practitioners of modern date who are quite as illiterate, even in these days of superior educational advantages. The reason is not far to seek. The standard of general education at most of our qualifying bodies is by no means a high one; indeed, many are satisfied with lower attainments than are expected at the Cambridge and Oxford local examinations for junior boys and girls, and faults in writing on professional subjects scarcely justify medical examiners in plucking the candidate afterwards. We will not touch on the much-debated question of the necessity of Greek in these examinations, although such a slight knowledge as will explain some of our medical terminology is a very valuable acquisition, and one requiring but little time and application on the part of schoolboys. We urge more particularly the necessity of an average English education and the testing of candidates in such subjects as composition and writing from dictation. Although these form parts of elementary education at every national school, they are much neglected at many higher-class ones, and do not enter into the examinations in Arts of several of our qualifying bodies. Were these to be insisted on, we should not be scandalised by seeing "ware" for "where," "linament" for "liniment," and "or*k*itis" for "orchitis," as we have noticed within a very few weeks. Again, the system of continually giving extracts from the same portions of a Latin author is greatly to be deprecated. At one examination the first two books of Cæsar's Gallic War have been set since the initiation of the Preliminary in Arts fourteen or fifteen years ago. Of course, by dint of coaching and cramming, a most inferior man must ultimately pass therein, even if he fails at his three or four early trials. The time and energy required to pass the later examinations, and to gain an average knowledge of the subjects of the medical curriculum, are a sufficient tax on a well-educated student, so that medical teachers are fairly entitled to demand that those who cannot pass an average standard should be prevented from entering our medical schools.

It might have been the wiser course to have looked into these examinations in Arts even before the professional ones, for the effect of the recent suggestions must make it a still more difficult task for an ill-trained and illiterate student to obtain his diploma, and it is no hardship to stop such an one at the very commencement of his attempts to enter the profession, whereas repeated failure becomes a very serious consideration to him and his family when he has spent two or three years in medical study. It is then frequently too late for him to turn his attention to some other occupation, and he strives on and on, a continual worry to teachers and examiners, until he passes, through some lucky chance, or, more generally, has to swell the list of unqualified assistants.

The general culture of the mass of the profession is infinitely superior to that which existed previously to the introduction of these preliminary examinations, but there is still room for improvement, in order that they may keep pace with the educational advantages of to-day, and the rapid reforms of the professional examinations.

In his valuable paper in the scientific reports of the Medical Officer of the Privy Council, Dr. Creighton has dealt with the question of the origin of cancer from another side to that taken in the discussion at the Pathological Society last year. In that discussion, enriched as it was by the speeches of so many of the foremost men in the school of English pathologists, the question was dealt with in great measure upon clinical grounds alone; the result being that opinions were equally divided between the view of a purely local origin of the disease and a constitutional one. Dr. Creighton, carrying on his researches at the Brown Institution, has studied carefully the histological features of the disease, and the results of his inquiry not only go far to upset the doctrines of Virchow on this head, but also lead to some highly suggestive hypotheses as to the origin of primary malignant tumours. Using the term "cancer" in its widest sense so as to include not only those malignant growths which arise primarily from epithelial surfaces, but also the vast group of the sarcomata whose origin lies in the connective tissues, Dr. Creighton commences by stating the results of his examination of growths in the liver secondary to those arising in the skin, bones, uterus, spleen, &c. The study of the formation of these secondary formations throws light upon the probable mode of origin of at any rate one great class of malignant tumours—the true cancers.

The mode of origin of secondary tumours is still a matter of debate. Many hold that they arise by the direct transference of the cells of the primary growths to the seats of the secondary formations; while others, including VIRCHOW, maintain that there is a transformation of the pre-existing elements of the part into cells similar to those forming the primary tumour. VIRCHOW, however, holds that it is only the cells of the connective-tissue framework that are so transformed, the highly specialised epithelial elements of the infected organs undergoing no change. Here, indeed, is the great point of divergence between the views of VIRCHOW and those held by Dr. MOXON in this country, and confirmed by the author of this paper. Reinstating "vacuolation" into the place from which Dr. BEALE, two years ago, had removed it, Dr. CREIGHTON avers that this is the first change undergone by a liver-cell on its way to be transformed into cells similar to those composing the tumour, be this myxomatous, lymphomatous, epitheliomatous, or what not. Vacuolation is, in fact, the first stage of endogenous cell-formation—a mode of cell-multiplication which has received far less attention than it merits. Briefly, the process consists in the conversion of the greater part of the protoplasm of the gland-cell (in this instance of the liver) into a highly refractive material, probably of fatty nature, the remainder of the protoplasmic contents being either displaced to the periphery of the cell, or remaining free in the centre of the cavity formed by vacuolation. It is from this protoplasm, the vital properties of which are manifested by its deep colouration with staining reagents, that, by an endogenous process, new cells are formed, at first round and "indifferent," later assuming the specific forms characterising the cells of the primary tumour. Of this process, with various modifications, Dr. CREIGHTON has traced the progress in all its stages by examining growths in the liver of various size and development. All growing tumours in this organ are surrounded by a zone of indifferent cell-growth and by columns of liver-cell in the stage of vacuolation. The process is then a truly metaplastic (or heteroplastic) one, taking place in the protoplasm of the liver-cell under the influence of the primary growth—an influence which he terms "spermatic," the changes that occur in the liver-cell being strictly comparable with the metaplastic changes that occur in the ovum after impregnation. It will be seen by this that the connective-tissue framework of the infected organ plays no part in the process, nor does it even in the formation of a stroma, which is so frequent a character of some tumours, this also being formed from the remnants of vacuolated cells.

So far, then, for the formation of secondary tumours. There can be little doubt that there is a true genetic relation between them and the primary growths. But what light does this throw upon the nature and origin of the latter? To clear up this, which, in truth, is the point of most importance both clinically and pathologically, Dr. CREIGHTON points out that vacuolation is a natural process. The products of secretory glands are all probably formed by some such process taking place in the gland-cells themselves. The secreting cell becomes filled with its peculiar product by undergoing a process of vacuolation; and the product—be it mucus, milk-globule, or spermatozoon—is distinctly a new formation, differing from the primary protoplasmic contents of the parent cell. Should the process of cell-transformation be arrested (it may be naturally, as in the involution of the mammary gland) or perverted, the resulting products are different; the solid or protoplasmic part of the cell gives rise to new cell-forms, and in some such way a new heteroplastic growth—as cancer—may arise. Here we have, then, yet another example of morbid products resulting from perverted natural processes, and, we may add, one other link in the chain of evidence in favour of the local origin of cancer. There yet remains unsolved, however, the question as to the exciting cause of this change. Dr. CREIGHTON proposes to follow up these researches with others bearing upon the development of mammary cancer, with special reference to the processes of involution and evolution of the gland; and, when completed, they cannot fail to be of the highest value, and are calculated to throw yet more light upon one of the most obscure points in pathology.

◆

WE are glad to take an early opportunity of referring again to the subject of Charity Voting Reform, inasmuch as it appears that since the last annual meeting of subscribers to the Royal Medical Benevolent College the position of the reform party has been considerably strengthened. It is reported that no less than 2101 names now appear on the memorial in favour of abolishing the present objectionable system of voting and canvassing; so that, as it appears, only about 300 remain who desire the continuance of things as they are. If this be the case, we counsel those interested in this question (and they are many) to take steps to call a special general meeting of the subscribers, as the matter is now ripe for final decision. It is eminently proper that this College should be in the van of reform, and should set an example that will, as we believe, be speedily followed by larger charities, both in London and the provinces. It is not necessary to recapitulate the evils of the present system, for they have been described and summarised over and over again in these pages. But we have received lately a copy of a letter on the subject addressed to the Board of Management of the Governesses' Benevolent Institution by Lord SHAFTESBURY, Justice JAMES, and the Recorder of London. These gentlemen represent on this occasion the Charity Voting Reform Association, and the letter indicates, as regards the Governesses' Institution, that, although the number of subscribers in favour of reform is as eight to one, the Board of Management decline absolutely to entertain the question of change in the present system of election. As the letter fitly puts it, this is a singular position to be taken by a representative committee. The Board is indeed a permanent and self-elected body, filling up its vacancies without being subject to any election by the subscribers at large. But if its representative character be acknowledged, a direct reference to the entire constituency of the charity should be made by it, and action taken on the result. It is evident that the cause of charity voting reform is, perhaps slowly, but surely gaining ground, and it will always receive at our hands hearty support.

Annotations.

"Ne quid nimis."

THE PUBLIC MEDICAL SERVICES.

The time is fast approaching for the competitive examinations to be held for the Medical Services of the British and Indian armies and that of the navy. The first-named service is scarcely likely to attract any number of candidates with the large amount of discontent existing in it at the present time, and the utterly uncertain character of the remedies, if any, which Mr. Hardy is to introduce when he has definitely made up his mind. Medical officers complain bitterly of the treatment they received from the last Government. They allege that the spirit and letter of the contract which was made with their service have been violated, that they were summarily deprived of their regimental appointments and of certain privileges in a way that would not have been attempted with the officers of any other branch of the service, and that so far nothing has been done to expedite promotion or otherwise improve their position. On the other hand, a great deal has been effected in the Naval Medical Department, which is now, in our opinion, far in advance of the Military Service, and we would strongly advise intending candidates to make themselves acquainted with the terms proffered to young medical men by the Admiralty. Lastly, there are the Indian Medical Service appointments, which are not by any means so highly esteemed as they once were. Still this service attracts a good class of men, and, spite of many well-grounded sources of discontent, it offers, in our opinion, many advantages over the Medical Department of the British army.

"PASS" AND "PLUCK" AT THE COLLEGE OF SURGEONS.

In another column will be found the report from the Court of Examiners of the number of candidates who have presented themselves for the Primary and Pass Examinations for the diploma of Member of the College of Surgeons during the collegiate year 1874–75, showing the number passed and rejected from each medical school during that period.

The general results are better than those of last year, but not so good as those for the year 1872–73. During the past year, of 727 candidates who presented themselves at the Primary Examination, 223 were rejected, or 30·5 per cent. In the previous year at the same examination there were 683 candidates and 242 rejections, or 35 4 per cent.; whereas in the year 1872–73 there were 702 candidates, with 199 rejections, or 28·3 per cent. For the Pass Examination last year there were 518 candidates, of whom 126, or 20·4 per cent., were rejected. In the year 1873–74 there were 456 candidates, with 124 rejections, or 27·2 per cent.; and in the year 1872–73 there were 461 candidates, of whom 85, or 18·4 per cent., were rejected.

It is impossible to accurately compare the merits of the different schools from these statistics, as the numbers of candidates vary greatly. To take, for instance, the medical school at Cork. There were no rejections in the primary examination, but then there was only one candidate. On the other hand, the Kingston School showed the highest percentage of rejections—namely, 100. Here, again, there was only one candidate, and he was unfortunate. Several schools each sent ·50 candidates, and as ·50 were successful the percentage of rejections was 0.

For the primary examination, Guy's has the fewest rejections—15·3 per cent. out of 78 candidates. Charing-cross stands next, with 18·5 rejections, but there were only 13·50 candidates. The rate appears to have been very high at St. Thomas's—56·7 per cent.,—and with the Westminster candidates it even reached 80 per cent. This is certainly very unsatisfactory, considering that only 10 candidates presented themselves from the latter school. Surely either teachers or students have cause for complaint.

Of the Provincial Schools, Manchester, with the greatest number of candidates (33·5) has the smallest number of rejections (16·4 per cent.) Cambridge is next; while Sheffield has once more the unenviable position of being the highest on the scale, having 70 per cent. of rejections. No conclusions can be drawn from the Irish schools, as the numbers are too small and unequal. With the exception of Edinburgh, which has 17·05 per cent. of rejections in 28·3 candidates, the Scotch schools stand low, Glasgow having a percentage of rejections of 61; and Aberdeen of 47·05.

In the Pass Examination, University College bears the palm, with 69·16 candidates, and only 10·8 per cent. of rejections. St. Bartholomew's comes next, with a percentage of 17·9 out of 61·3 candidates. The three highest percentages of rejections in the metropolitan schools are St. George's, with 30 999 per cent. out of 27·50 candidates; King's College, with 44·06 per cent. out of 29 50 candidates; and Charing-cross, which rises to 55·5 per cent. with 4·50 candidates. Manchester is, in the second examination, again at the head of the provincial schools, having only 10·7 per cent. of rejections; Cambridge is second; while Birmingham has 58·3 per cent.

THE ROMAN ACADEMY OF MEDICINE.

The first meeting of this scientific body took place in the hall of the University of the Sapienza on the 27th June. Besides thirty-three ordinary Fellows, there were present the Minister of Public Instruction (by deputy), the Rector of the University, and a considerable number of physicians, medical students, and the non-professional public. Prof. Maggiorani, one of the most distinguished teachers of the Roman Medical School, presided and delivered an address, wherein he stated the objects for which the Academy had been instituted. He pointed to the ceaseless march of medical induction, and vindicated the value of free discussion in guiding and steadying its steps. Medicine, he argued, is rapidly becoming coextensive with the science of humanity, and its investigations are acquiring the most living interest for the legislator. Society, moral as well as physical, must rely, in the last resort, on the guidance of medicine in that enlarged sense in which the physician's art is now studied and practised. Take, for instance, the notorious case of Louise Lateau. Millions of people were being deluded into the belief that the woman was the subject of miracles, and superstition was pointing triumphantly to her symptoms as evidence of the visible working of the "spirit," till the Belgian Academy of Medicine brought science to bear on the phenomena, and reduced her periodically bleeding stigmata, her ecstatic fits, her somnambulism, and her hearing of voices, to physio-psychological law. No institution but an Academy of Medicine could have investigated the case so thoroughly or pronounced on it so authoritatively. But this is only one use of Academies. The physician in daily practice benefits by them in maintaining the "scientific attitude" so apt to be lost in the distractions of extra-professional detail, while the investigator comes to them from his laboratory to profit by the criticism his conclusions evoke from the practical mind. Useful in all great centres of life, such an Academy is peculiarly so in Rome, where prescriptive authority has so long impeded the movements of a professional class pre-eminently fitted for scientific research. The discussion that followed Prof. Maggiorani's able address gave ample proof of the interest with which medicine, theoretical and practical, is prosecuted in the city of Galileo and Lancisi, and we may anticipate from the Medical Academy of Rome the best of all assurances that biological science maintains its rightful place in the second Renaissance which Italy is passing through.

A SECOND OCCUPATION.

Another authoritative voice in the profession speaks out in favour of the view that society is suffering, not from overwork, but from underwork. Dr. Wilks, in his paper on Overwork, in The Lancet of June 26th, which should be carefully read, says that in his experience more ailments arise from want of occupation than from overwork, and, "taking the various kinds of nervous and dyspeptic ailments which we are constantly treating, I find at least six due to idleness to one from overwork." The question is a very serious one, and one that will well repay the attention of medical men. Our own opinion is strongly in favour of Dr. Wilks's view, that the healthiest people—i.e., people with the *mens sana in corpore sano*—are the men and women whose time is most fully occupied, those who have what Dr. Wilks happily calls a second occupation to fall back upon when the main occupation does not press. Our own profession is rich in men who have second occupations, and have even distinguished themselves in them, and our present House of Commons would supply some good examples. Lord Palmerston, one of the most hard-working of men, found his rest not only in sleep, which with him was sound at nights, but in acquainting himself with the latest indications and discoveries of science. Dr. Wilks goes so far as to say that even the occupations of fashion and frivolity are better than none, and no doubt he is right; but woe to those who find their main employment in these, greatly for this reason, that they render the mind indisposed for a second occupation, which ought to be one engaging the intellect and the senses, though in ways different from those of ordinary work.

HOMICIDE BY INFECTION.

Whether Elizabeth Marsden, in the course of imprisonment for conveying puerperal fever, and in it death to several of her patients, is a martyr or a justly punished criminal, is a question on which opinion in the profession is divided. It is evidently part of a much larger question involving issues of considerable consequence to the profession. On any view, good will arise from the prominence given to the culpability of continuing obstetric practice after it is clearly apparent, or even probable, that the poison of puerperal fever attaches to the practitioner. The Forfarshire Medical Association has petitioned the Home Secretary for Marsden's release, on the ground that in the present state of medical doctrine as to the numerous questions connected with puerperal fever the charge of homicide by puerperal infection cannot be scientifically proved, and that it is without precedent in criminal jurisprudence. The Association admits that she acted at variance with ordinary prudence. This is too mild a way of expressing her culpability. She disregarded the best advice, and a series of facts which should have impressed even an ignorant woman. Though, as we have already pointed out, we think the process of dealing with this new offence in law admits of abuse and misapplication, we cannot acquit Marsden of most serious blame. Mr. Wells, it will be seen, in his summing up of the late discussion at the Obstetrical Society, strongly deprecated the attempt that had been made to enlist the sympathy of the Society on behalf of such cases, and inculcated even extra precautions, so that the life of not one puerperal woman may be endangered. This is the right note to strike on this serious question, and we may feel pretty well assured that no practice honestly and carefully conducted will come within the notice of the law. We are far yet from being in any danger of overdoing the precautions of cleansing, disinfection, &c., necessary to avoid the chance of conveying disease. Let us err in the direction of excessive caution. It is lamentable to hear, as we have very lately heard, that in Vienna, where the connexion between the dissecting room and puerperal fever has been long apparent, remarkable recklessness on the subject still exists, and as a consequence great puerperal mortality.

MR. TEALE'S CASE OF HIGH TEMPERATURE.

Although five months have elapsed since notes of a remarkable case of high temperature were read before the Clinical Society by Mr. G. Teale, yet the case was in itself so subversive of all current ideas on the subject that we doubt not it is still fresh in the memory of our readers. With commendable candour the author of that paper has just addressed a letter to a contemporary in which he replies *seriatim* to several very natural queries that have been put to him concerning the facts of the case, and the possibilities of any artificial means within reach of the patient of raising the index of the thermometer. From this it would appear that observations were taken in mouth and rectum as well as in the axillæ, with the result of showing the same high level (110° to 120°); that the rise in the thermometer was sometimes noticed at the time; that no hot bottles or blankets were in contact with the patient by which she could have artificially warmed the thermometer; and that the instruments used had been tested and found correct, and had during the recovery of the patient registered normal as well as abnormal temperatures. As we ventured at the time to question the possibility of the maintenance of life at such a high rate of temperature (unaccompanied as it was by any extreme variation in pulse and respiration frequency), so do we now cheerfully accept Mr. Teale's further explanations, which seem to leave nothing to be desired in testimony of the faithfulness and accuracy of the record; while at the same time it leaves the *modus operandi* in as mysterious a condition as ever, and goes far to expand our hitherto too narrow notions. Exceptional and full of mystery the case must remain, and that another of like nature will occur is to be hoped, lest we may have to consign it to that limbo of "exceptions" which go to prove the rule, the rule in this instance being the incompatibility of animal life with a body heat of 120°.

THE CLINICAL STUDY OF INSANITY.

A document having the form of a petition, to which are attached the signatures of seventeen teachers of psychological medicine, has been forwarded to the various examining boards of the kingdom, praying them so to modify the existing regulations as to the amount of clinical study required from their candidates, that they may resemble the regulations of the University of London, which are as follows:—"Attendance during three months in the wards of a lunatic asylum may be substituted for a like period of attendance on medical hospital practice. The Senate regard it as highly desirable that candidates for the degree of M.B. should practically acquaint themselves with the different forms of insanity by attendance in a lunatic asylum." We heartily concur with the "petitioners" in their "prayer," and we doubt not that if the option were given to students of doing some of their hospital work in lunatic asylums, many would avail themselves of it. In a lunatic asylum, although a student would learn a great deal that was special, he would at the same time come across very much which appertains to general medicine and surgery, so that this short time devoted to lunacy could not be considered as wholly deducted from the ordinary curriculum. The only drawback to the plan at present is the fact that asylums are not very conveniently situated for students, and we can hardly concur in the statement of the petitioners that "there is at least one contiguous to evèry medical school in the kingdom," unless the interpretation which they place on the word *contiguous* be very different from that which is usually applied to it. We must demur also to the statement that "paralysis, softening and tumours of the brain, chorea, hysteria, hypochondriasis, and others" are diseases not *usually seen* in general hospitals. Those specified are perfectly common in all general hospitals, and as for the "others" we may infer that they also are to be met with. Notwithstanding this slight overstatement, we are sure that those who have signed this document have right on their side, and we trust it will receive the serious consideration of the bodies to whom it is addressed.

THE ARTISANS' DWELLINGS BILL.

A scheme which (notwithstanding that it is somewhat informal and not in accordance with the letter of the Act) seems to us a plausible and a good scheme, has been laid before the Board of Works for the Holborn district by their surveyor, Mr. Lewis H. Isaacs, having for its purpose the improvement of that miserable district adjoining the Gray's-inn-road, of which the notorious St. Alban's Church is the centre. The plans accompanying the scheme—which at present, be it remembered, is merely the suggestion of one man, and has not been sanctioned by any authority—are seductive to look at, and are not at all unlikely to go far in convincing those interested that the adoption of this or a similar plan is strongly advisable. Between Gray's-inn-lane and Leather-lane is a labyrinth of foul courts, which is the chosen home of every form of physical and moral depravity. Mr. Isaacs wishes to sweep about twenty of these close courts, which shelter nearly 4000 persons, entirely away, and in their place he proposes to build, grouped round St. Alban's church as a centre, five large blocks of artisans' dwellings. The plan further involves the making of two new streets and the widening of Leather-lane and of the narrow part of Gray's-inn-lane, as well as of other less-known thoroughfares. The scheme at present is crude in the extreme, and in the absence of estimates as to cost and the probable return on outlay, it is impossible to say more than that, from a hygienic point of view, it appears admirable, and if it be carried out there must to a certainty be a dividend in the shape of improved health.

ACTION OF ACONITINA UPON THE HEART.

Lewin, operating on frogs, finds that aconitina, in doses of ·0025 to ·0015 gramme, lowers the frequency of the cardiac beats and this occurs most rapidly when injected into the veins, more slowly when subcutaneously injected, and most slowly when injected into the stomach. The duration of the action varies from one to two hours. It is succeeded by a period of increased frequency of the heart's beats, which is soon followed by irregularity, and, finally, ends in arrest in diastole. At the close of almost all the experiments an arhythmia of the cardiac actions occurred, due to the rapid pulsation of the auricles or to their beating alone. The peripheral nerves, when the poison was administered in moderate doses, exhibited considerable diminution of excitability, and with larger doses paralysis occurred. The heart after death did not always respond to electrical excitation. In experiments on warm-blooded animals, he found that the first symptom observable was marked dyspnœa, and this augmented till death occurred; but by the application of artificial respiration for nine hours and a half continously he was able to save the life of a rabbit to which a fatal dose had been given. The dyspnœa is due to the direct action of the poison on the respiratory centre in the medulla oblongata. In regard to the heart, he obtained results of a double nature, partly conformable to those produced by digitalis (corresponding therefore to primary irritation and subsequent paralysis of the vagus), partly consisting in a diminution of the force of the heart and a rapid sinking of the frequency of the pulse. The cause of this was the action of the poison on the ganglionic centres in the heart, at one time with integrity of the vagi, and then with paralysis of the vagi.

THE HEALTH OF THE POPE.

On Monday, the 5th inst., Pio Nono held a long and fatiguing Consistory, after which he gave thirty distinct audiences, and yet at the close of the day his lightness of step and conversational vivacity were something remarkable. Without attributing this bodily and mental vigour (as the *Osservatore Romano* does) to a miracle, the phenomenon is interesting enough to deserve comment. Pio Nono's physicians have recently prescribed him daily baths of sulphur-water, brought all the way from Civita Vecchia for the purpose. A large bathing contrivance, something like a diminutive reservoir in size, has been expressly constructed for him, and into this he descends by a little staircase, and then takes his seat in a chair, while the water gradually rises around him. Thus he sits for half an hour, the Fra Salvatore carefully manipulating the open issues in his Holiness's lower extremities, and another member of the Pontifical household attending to his wants. On coming out of this artificial sulphur-spring, or *bulicame*, as the Italians call it, the Pope is served with some strong soup in which a capon has been boiled down, and with this he takes a glass of Johannisberg cabinet, or Romanée Conti. Under this treatment he braves the excessive heat with comparative impunity, and can often dispense with his staff in walking. The issues continue open, but probably on that very account he has for many weeks been free from those epileptoid seizures to which he is constitutionally prone.

NOXIOUS FUMES FROM FACTORIES.

It is earnestly to be hoped that the Public Health Bill which will shortly become law will provide an efficient remedy for the abominable nuisance now caused in many populous districts by the noxious emanations from chemical manufactories. Three great associations, the South-Eastern of London, the Northumberland and Durham, and the Lancashire and Cheshire, have worked in unison with the utmost zeal to induce the Government to incorporate in the measure a sufficient remedy for the evils complained of. Some few of the amendments suggested by the associations have been adopted, but others have been ignored, so that the actual working value of the new enactments must remain for the present a matter of doubt. An uncertain and expensive remedy exists, of course, at the present time. An injunction in Chancery may be sought, and is generally granted if the fact of a nuisance is clearly established. It is not necessary to prove injury to health, or even injury to property. The Lords Justices hold that a man has no more right to pour foul air over your premises than he would have to pour foul water, and several recent decisions have affirmed this view. But it is only those who are rich as well as brave who venture on proceedings in Chancery, and meantime the grievance is widely felt. No doubt the three associations to which we have referred will take care that the powers of the new law shall soon be thoroughly tested, and we await their action with interest. Urban authorities, at any rate, will now have the power to act, and it is possible that they may prove equal to the occasion.

If they grapple with the evil, and succeed in suppressing it with the machinery they will soon be able to command, they will give a powerful illustration of the value of local government, and will quiet the fears of those who think that the new measure will prove to be another piece of sham legislation.

HAMPSTEAD FEVER HOSPITAL.

THE Select Committee of the House of Commons, appointed to inquire into the action of the Metropolitan Asylums Board with reference to the Hampstead Hospital, held its first meeting on Friday, the 9th inst. The committee consists of Mr. Sclater-Booth, chairman, and Messrs. Coope, Collins, Goldney, Hayter, Locke, A. Reed, Pell, Pemberton, Ralli, and Ritchie. The first witness examined was Mr. Wyatt, the chairman of the Hampstead Hospital, who read a long statement prepared by the Asylums Board in defence of their conduct in the matter, and giving a detailed account of the action of the board with reference to the provision of accommodation for epidemic diseases since its constitution. Mr. Wyatt's evidence did not disclose any new facts or arguments, with the exception of an admission that the main objection to the last proposed alternative site was the outcry raised about the possible contamination of water-supply from its nearness to the reservoir. Dr. Sibson, who was a member of the Asylums Board from its formation until 1868, and to whom the general plan of arrangement of the situation of the hospitals was due, was also examined, and gave an account of that plan, which consisted in having three hospitals at the corners of a triangle, each of which was to be within three miles of the locality from which the patients were drawn. He stated that the sites were chosen on account of their being away from the population. His opinion was opposed to the idea of any danger existing from the neighbourhood of a hospital to a reservoir, if the latter were on a higher level. Dr. Bridges, of the Local Government Board, who was afterwards examined, pronounced in favour of the Hampstead site. The committee have decided not to hear counsel; but the inquiry is likely to last some time.

THE BIRMINGHAM CORONERSHIP.

MUNICIPAL government, although an admirable system in theory, occasionally commits some egregious blunders, and makes itself appear ridiculous. Seldom has a more striking proof of its failure been afforded than in the recent election of a coroner at Birmingham. For a very long period Dr. Birt Davies had filled that office with credit, and on his retirement the Corporation testified its appreciation of Dr. Davies' services by giving him a very handsome vote of thanks. We should have thought that a medical man would have been regarded as his most natural and most probable successor, as the Corporation attached unequivocal importance to the special medical attainments which their late coroner possessed in so eminent a degree.

A very different policy has, however, been pursued. After advertising for candidates for the vacant office, a considerable section of the Town Council met and drew up a memorial to Mr. Hawkes, an elderly solicitor, asking him to become a candidate, and promising him their support. On the day of election Mr. Hawkes was allowed to walk over the course, all the medical candidates who might have filled the office with advantage to the town having retired. After this one may reasonably doubt whether corporations ought to be trusted with such important functions as the election of coroners.

SANITARY CONDITION OF BAGSHOT.

NOT long ago we alluded in strong terms to the disgusting condition of the village of Bagshot. Though situated in one of the healthiest spots in England, this unfortunate village has long remained in a state that would scarcely be tolerated even in an Oriental country. The only water-supply of many of the cottages is derived from a stream which is little better than a common sewer, and the few wells that we saw are exposed to an almost equally direct pollution. The Local Government Board has now taken the matter in hand, and something is at last to be done. Cesspools and drains are to be constructed; sewage is to be kept from the stream, and the latter then left "open to the public." Whether this reform will be a real one remains to be seen; but we are inclined to fear that such a stream, liable to all kinds of accidental and wilful pollutions, can never be a safe or satisfactory water-supply. It is something, however, that any kind of action has been induced.

THE KENT MEDICAL BENEVOLENT SOCIETY.

THIS Society celebrated its eighty-eighth anniversary at Maidstone on Thursday week, W. Hoar, Esq., presiding, supported by Drs. Lowry, Price, Carr, and Moncton, and Messrs. George Rigden, Wood, Joy, Hallowes, Hubbard, &c. &c. The report stated that the number of members exceeded that of any previous year, being 164; the deaths and withdrawals, 6; whilst the new members were 9. The income of the Society from subscriptions, donations, and the interest of funded property amounted to £403 13*s*. Two new applicants for assistance were placed on the list, making, with the annuitants of the previous year, ten in the receipt of grants, the amount given being £410. The largest sum granted to an annuitant was £80, the smallest £10. The death of the treasurer, Henry Denne, Esq., was announced; his successor, George Rigden, Esq., being elected to fill the post. The expenses of management are about £30 annually; the subscription £1 1*s*. a year. Its claims being purely philanthropic, and based on the principle of self-help, this Society ought to embrace every medical man in the county.

M. RICORD.

WE understand that M. Ricord is about to pay a visit of longer duration than usual to England and Scotland; and that he is likely to be the guest of Mr. Acton, in Harley-street, for a few days in the early part of August. Our illustrious and venerable *confrère* has sustained a heavy loss by the death of his bosom friend, Demarquay; and he seeks consolation in change and travel.

PEPTONES AS A FOOD.

IN a communication made to Pflüger's *Archiv*, MM. Plósz and Gyergyai, from a series of experiments recently performed, state they have ascertained that an animal fed on peptones can increase in weight, and, secondly, that nitrogenous compounds are laid down or deposited in the body. There is hence no absolute necessity that albumen should be absorbed in an unaltered condition, though this is by no means impossible. They have further shown that when peptone is absorbed it quickly undergoes change in the organism, though it cannot be positively stated whether it undergoes conversion into albumen, or whether it undergoes other changes, the albumen in the body proceeding by the action of cells from the products of its disintegration combined with other constituents of the body. They are unable to state when this change occurs. It does not appear that oxygenation plays an important part in the process.

THE QUEEN'S HOSPITAL, BIRMINGHAM.

The special meeting of governors, held on the 9th inst., for the purpose of considering the advisability of adopting the free system, with registration, inquiry, &c., after hearing the objections of the delegates from the working men's meeting held at the Committee-room of the Town Hall, and presided over by Mr. Gamgee, and also the arguments adduced in favour of the free system by the present and late chairman of the hospital, Dr. Heslop, and others, decided, on the recommendation of Mr. Muntz, to adjourn the discussion of the subject until November next, so as not to endanger the Hospital Sunday collection, which this year falls to the lot of the Queen's Hospital, and to give further time to the governors to consider the importance and value of the proposed changes in the administration of the hospital.

ELIMINATION OF ALCOHOL BY THE RESPIRATION.

Aug. Schmidt (*Centralblatt*, 1875, p. 371) states that, having read Henbach's late observations showing that little or no alcohol appeared in the urine of febrile patients to whom it had been freely administered, he resolved to submit the expired air to renewed investigation, and the result of his experiments is, that when 50 ccm. of absolute alcohol have been consumed, at most only a trace can be discovered in the expired air. This is in full accordance with the statements of Anstie and Dupré.

The Guardians of the Keighley Union have applied to the Local Government Board to defer proceedings in the matter of the *mandamus* to compel them to carry out the Vaccination Acts. We are glad to learn that the application was unsuccessful. The Central Authority, after refusing to concede to the request, advised the guardians to comply without delay with the requirements of the law, and thus render unnecessary any further proceedings on the writ, which could only result in increased cost and trouble to the local representatives. On the receipt of this communication a resolution was proposed, to the effect that the board accepted the decision of the judges, and pledged itself to give the necessary instructions for enforcing vaccination. The obstructive members, we regret to say, carried the day, and the resolution was lost, six voting for and nine against it. In the meantime small-pox is epidemic in the district.

The arrangements in connexion with the meeting of the Social Science Congress, to be held at Brighton, are now completed. Under the section of Health Department we find that the following questions will be discussed:—1. To what causes are to be attributed the ill-construction and want of sanitary provisions which exist in the dwellings of the upper and middle classes, and what is the best method which should be adopted to remedy and rectify the same? 2. What are the advantages or disadvantages of water-supply being lodged in the hands of local authorities? 3. What are the advantages of English, as compared with foreign, watering-places and health resorts? What are the best means for rendering the English watering-places more efficient, for obviating the dangers arising from the occasional introduction of infectious diseases, and for determining the annual rate of mortality in each district?

The Manchester and Salford Sanitary Association have forwarded a petition to Lord Derby for presentation in the House of Lords making various suggestions with reference to the Public Health Bill. It is recommended that clauses be inserted specifying certain fevers and other infectious diseases which shall be within the compass of the Act, and providing that such cases shall be speedily brought under the notice of the sanitary authority having jurisdiction over the area in which they occur, medical men to report immediately the appearance of infectious disease. Also that every local sanitary authority shall make monthly returns to the Local Government Board.

A Parliamentary return has just been issued, showing the cases in which the Local Government Board in Ireland have interfered in revising the salaries of sanitary officers appointed under the Act of last session. By this it appears that the authorities of thirty unions and of three boroughs fixed the salaries of these unfortunate officers at so low a figure that they raised at head-quarters in most cases as much as, and in some cases more than, 50 per cent., and even now seem to be but pittances.

In our notice last week of the election of Mr. Brudenell Carter to the Professorship of Surgery and Pathology at the College of Surgeons, we inadvertently referred to him as having been the only applicant for the office. This is an error. Mr. Carter was appointed to the chair, without solicitation on his part, on the nomination of a very distinguished member of the Council, on which circumstance Mr. Carter has our hearty congratulation.

The deaths in London last week amounted to 1400; and included 27 from measles, 58 from scarlet fever, 3 from diphtheria, 53 from whooping-cough, 15 from different forms of fever, 179 from diarrhœa, and 171 referred to diseases of the respiratory organs. Five deaths from puerperal fever were recorded in the period.

On Monday the Prince and Princess of Wales opened the new Children's Home at Norbiton, in connexion with the Metropolitan Convalescent Institution. The new Home will accommodate 150 children. We understand that the ventilating and sanitary arrangements of the building are excellent.

The presiding magistrate at the Greenwich Police Court has announced his intention not to impose fines in cases of adulteration of milk with water when it is not over 10 per cent. This determination cannot be said to be in strict accordance with the terms of the Act, and we shall probably hear more of the matter.

Mr. William Craig, of Maryport, Cumberland, formerly of Strathaven, Lanarkshire, who was admitted a Licentiate of the Faculty of Physicians and Surgeons of Glasgow in the year 1814, died on the 4th instant at the advanced age of ninety years.

In the House of Commons this week Mr. Hardy, in reply to Mr. Lyon Playfair, said he hoped to be able at an early date to publish the new regulations in regard to militia medical officers.

H.R.H. the Duke of Edinburgh has consented to become President of the Seamen's Hospital Society at Greenwich, and has presented the institution with a donation of thirty guineas.

A vessel has arrived in the West India Docks, from Mauritius, with several cases of scurvy on board.

THE Hospital Sunday Fund continues to receive valuable contributions. Not the worst Christians in this matter this year are the Jews, who have contributed in all £991 14*s.* 4*d.*, as against £950 14*s.* 11*d.* in 1874. We shall reserve our comments on the collection for 1875 till it is nearer completion.

WE understand that Dr. R. Beveridge, of Aberdeen, is a candidate for the vacant chair of Medicine in the University of that town. Dr. Beveridge appears to have strong claims for the appointment.

IN the House of Commons on Monday night the Medical Acts Amendment (College of Surgeons) Bill was read a third time and passed.

REPORT
OF
The Lancet Sanitary Commission
ON THE
SANITARY CONDITION OF OUR PUBLIC SCHOOLS.

◆

INTRODUCTORY—(*Continued.*)

HAVING reviewed the various circumstances that influence the health of schools, either from insanitary conditions of the neighbourhood in which they are situate, or from defective sanitary and domestic arrangements in the schools themselves, we pass on to a consideration of the nature and extent of the medical supervision that ought to be exercised over the boys.

Medical Supervision of Schools.

Generally speaking, one of the leading practitioners of the town or neighbourhood in which the school is situate is the ordinary school attendant. At Eton, Winchester, and Harrow the house master employs his own medical man to attend the boarders in his house. At Marlborough and Rugby there is a special medical man attached to the school, who not only attends to the boys when ill at all the houses, but advises on all matters connected with sanitary management. Whatever arrangement may be made, however, with regard to individual attendance on boys when sick, we think that one medical man should be specially attached to every school, whose duty it should be to constantly overlook the school arrangements and to make himself acquainted with the habits and constitutions of the boys. In small schools, or in places where it is difficult to meet with medical men having the necessary sanitary knowledge, the medical officer of health of the district, or nearest large town, should be invited to make a periodical visitation and report on the sanitary arrangements, and see that everything is in an efficient and satisfactory condition.

The system of medical supervision is most completely carried out at Marlborough and Rugby; and from what we saw at these schools, and at one or two others, we have been able to draw up a series of recommendations which we think might be adopted in every educational establishment. In the first place, on a boy's entering the school, the parent should be obliged to furnish correct information whether the lad has had any contagious disease, and if so of what nature, and the date of its occurrence; and whether there is any peculiarity of constitution that ought to be noticed. The boy should then be carefully examined by the school medical attendant, and his name, age, weight, height, and girth round the chest entered, together with the foregoing particulars, in a register. On leaving school for the vacation he should again be seen by the medical attendant, and his increase in height, weight, and girth carefully recorded. A certificate stating the condition of the boy's health during the past half-year should be sent to the parents, who should be obliged to furnish another on the boy's return, stating if the boy has been ill or not during the vacation, and if so it should be countersigned by the family attendant, certifying the nature of the disease. Dr. Frederick Smith, of Lewisham, has drawn up a useful Register of Health in which most of the foregoing particulars can be noted, and which will be found very convenient. We have been told that many of the above suggestions are not practicable, but we can only say that most of them are enforced at Marlborough and Rugby, and that the personal inspection of the boys at the beginning and end of each half is carried out at some of the naval schools. The advantages to be gained by attention to these details are manifest. Supposing scarlet fever or measles break out in a school, the medical attendant at once learns what boys have had the complaint by looking over his register, and can then judge how many boys there are who are liable to the disease, and make provision accordingly. By examining a boy on his return from the vacation the medical man would have a chance of detecting any contagious complaint which may have been overlooked at home. We have already shown that such oversights are not uncommon, especially with respect to mild cases of scarlet fever. The half-yearly record of the boys' increase in height, weight, and girth would be invaluable, and the medical attendants of our schools would soon be able from such observations to furnish us with important information with regard to the development at this epoch of life, besides being able at once to detect any changes in an adverse direction, and by timely treatment to arrest the mischief. Dr. Fergus, of Marlborough, tells us that, in many cases, "great benefit has resulted from sending delicate boys away for the spring term, and allowing them to return for the summer and autumn terms. This causes no loss of time, as it so much promotes the general health as to enable a boy whose constitution is weak to go through his school career and end his time successfully; whereas, if he had been exposed to the cold and trying weather of spring at school, he would probably have had some acute attacks which would shatter him for years." Again, heart affections not uncommonly gradually supervene in delicate and rapidly-growing boys when exposed to undue strain and excitement. Only an intimate acquaintance with the physical condition of each boy would enable the medical attendant to detect the mischief at an early stage, and to regulate the school-life accordingly, or to send the boy away for a term, or longer period, until his health and strength allow him to return. Lastly, every boy who is not in school ought to be in the sick house. This rule is strictly enforced at Marlborough, and Dr. Fergus finds that not only is all malingering checked, but, when needful, prompt treatment and immediate isolation can be secured if the case prove an infectious one.

We cannot leave this part of our subject without referring to the influence the school work and sports have upon the health of the boys. This is a point on which we think the masters might more frequently consult with the medical attendants. With respect to the work, we did not find at the large public schools that the amount required was excessive, or that any undue pressure was put on the boys. At many of the smaller schools and proprietory colleges, however, the system of cramming is unmercifully employed. These places, not having the prestige of the older schools, endeavour to secure public patronage by forcing on candidates for successful competition in every kind of examination. It is at these schóols the breakdowns are most frequent, and the cases that have been brought under our notice have been especially sad. The remedy lies with the parents. Schools having such reputations ought to be carefully avoided, for if a boy be clever he will be worked out to the last ounce, and if stupid it is probable that he will be altogether neglected. We think that the ordinary school work ought not to exceed more than six hours on whole school days, or more than four on half-holidays; before an examination, a senior boy might be allowed to extend the time to eight hours. We must condemn the practice, permitted at some schools, of allowing boys to sit up till ten or eleven o'clock in their studies or sitting-rooms; all work should be finished by nine o'clock, and none permitted after that hour, and the boys should be in bed before ten o'clock. With regard to the school sports, we find that, with the exception of Marlborough and Rugby, little or no supervision is exercised over the boys: the weak and the strong are allowed to engage in the same sports without any regard being paid to their physical capabilities. At Marlborough and Rugby the medical officer receives with each boy a statement from the parents of their son's previous medical history, with an account of any peculiarity of constitution. If the boy is considered weak and delicate, it is settled what games he may be permitted to join in, and to what extent he may follow them. Dr. Dukes, of Rugby, tells us that the Natural History Society established at that school engages the attention of those who are unable to join in the games, and gives them sufficient exercise in the pursuit of practical geology, zoology, and botany.

We have been asked to say a few words with respect to school punishment. The subject is both difficult and delicate. There can be little doubt that corporeal punishment often has an injurious effect on boys of a highly nervous temperament, and we think the master ought always to consider what the probable effect may be before resorting to it in any individual case. We think it ought only to be administered for immoral offences, indecent conduct, or for bullying. It ought never to be used for default in school work; at all events not till the diagnosis between idleness, natural stupidity, and ill-health is made a little more certain. No master should be allowed to box a boy's ears, or rap his head with his knuckles; very serious and even fatal results have frequently followed this punishment, and its practice has been generally abandoned at all the larger and better class of schools. Giving impositions for boys to learn or write out in their play-hours we think injurious, as it confines the boy to the school-house and prevents his taking proper exercise; punishment drill would be far preferable, as far as health is concerned, and we believe would be quite as effectual. Few boys would care to spend their half-holidays in marching up and down a flagged court-yard, and going through that monotonous exercise known as extension drill. Indeed, from our own remembrance of the drill-sergeant, we think boys, if they had their choice, would prefer the imposition, over which they can dawdle at their own discretion.

THE COMPARATIVE ANATOMY OF THE PLACENTA.

By PROFESSOR TURNER.

In his third lecture (June 16th) Professor Turner described the formation of the zonular placenta which is met with in carnivora, in the seals, and in the hyrax and elephant. As but little is known concerning its minute structure in the two last-mentioned animals, the lecturer limited himself to the carnivora and seals, premising that this form of placentation was far more complex than either the diffuse or the cotyledonary form, and required much careful study to make its anatomical analysis.

The gravid uterus of the carnivora is bicornuate; each horn containing two or more fœtuses, each of which again is enclosed within a separate compartment of the uterus, and is provided with its own membranes. Professor Turner has examined the placentation of the cat at different periods of gestation with the following results:—A few days after impregnation, when each compartment measures about eight-tenths of an inch in length, the series of compartments looking like a string of beads, the chorion, with its still simple or but slightly branched villi, is readily detached from the mucous membrane. Already, however, the uterine mucous membrane is seen to have a different character at each pole (for about one-tenth of an inch) of the compartment from that which it presents between these parts, being smooth at the poles, but elevated, thick, and spongy, and studded with the minute apertures of the crypts in the intermediate part.

Speaking of the relation of the utricular glands to these crypts, Prof. Turner stated that there was no question that a large number of the latter, if not all, were new-formed structures, as shown in those animals with diffuse placentation. The glands lie immediately subjacent to the crypts, and may either have independent apertures, as in the ruminants, pig, and mare, or some may open into the crypts; but there is much difficulty in the investigation of this point, owing to the modified condition of the surface of the mucous membrane. The crypts, however, far outnumber the glands; and each of them is lined by a layer of epithelium supported by a vascular sub-epithelial connective tissue, as in those animals previously described.

Passing now to a later stage—namely, when a uterine compartment measures about 1½″ in its long diameter,—the chorionic villi are found to be more restricted in their distribution, and the crypts also are limited to a narrower middle segment of the compartment. There has been a recession from the poles towards the centre. So far, however, it has still been possible to detach the villi from the mucous membrane. Later still, there is a very considerable portion of the pole of each chorion free from villi, which now come to be limited to the middle third of that structure; the altered mucous membrane being similarly limited; and in this later stage the separation of the fœtal from the maternal part of the placenta becomes impossible.

Vertical sections through the fully-formed placenta show a complete interlocking of the branched villi with plates of the maternal tissue, representing the walls of the crypts, the villi reaching nearly to the surface of the mucous membrane, and the intervillous laminæ passing up to the surface of the chorion. On horizontal section, each villus is now seen to be much branched and sinuous, and to be bounded accurately by the modified crypt walls. Hence there comes to be a mechanical difficulty in the separation of the fœtal villi from the walls of the crypts, and it is this which has caused these animals to be placed among the Deciduata. The maternal laminæ consist of a basis of connective tissue freely supplied with vessels, in part capillary (as in the mare, cow, sheep, &c.), in part composed of larger trunks twice or three times the diameter of the fœtal capillaries. It is, in fact, the first indication of a sinus system in the maternal placenta. The epithelium of the crypts is columnar or irregularly polygonal in shape, the cells in the cat being peculiar in having a highly refractive nucleus.

The placenta of the cat when shed presents a perfectly smooth appearance on its uterine surface—a character due to the fact that the whole or a great part of the mucous membrane is cast with the placenta.

The placenta of the bitch resembles that of the cat in its general characters. However, the whole of the mucous membrane is not shed, and a ragged flocculent surface is left from the tearing across of the intervillous processes.

In the fox the formation of the placenta follows the same plan as in the bitch, but here the maternal vessels are more dilated, and are of colossal size as compared with those of the dog. All the epithelial cells of the crypts in the fox are columnar and of great size.

Passing to the placentation of the seal, which was illustrated by a very fine specimen from the College Museum, Prof. Turner showed that the uterine surface of the placenta in this animal was very ragged and irregular, owing to a very large amount of mucous membrane being left on the uterus when the placenta is detached. In this respect, then, the seal resembles the dog rather than the cat. The placenta is divided by means of deep fissures into convolutions, each of which is subdivided by smaller fissures into lobules. The processes of maternal tissue are here greatly modified, passing up as thick vascular bands in the fissures into the substance of the placenta, where they surround the groups of ramified villi. There is further a remarkable anastomosis of the chorionic villi with each other at the periphery of the lobuli, so as to enclose the finest processes of the maternal tissue. This arrangement is almost ordinal in its peculiarity.

Prof. Turner then formulated the following general conclusions:—1. That in studying the placenta its compound nature (fœtal and maternal) must be kept in mind. 2. That the maternal part is nothing but the modified mucous membrane of the uterus, but is of more complex nature to start with than the simple chorionic villi of the fœtal portion. 3. That a whole series of crypts is developed in the mucous membrane for the reception of the villi; these crypts being simple, or branched, as in the pig, mare, cetacean, and ruminants; or sinuous (as in the cat), or (as in the seal) subdivided into primary, secondary, and tertiary structures, till the whole mucosa is split up into a microscopic network. 4. That the crypts are not developed from the utricular glands, but are new interglandular formations. 5. That the "decidua serotina" (or that portion of the maternal mucous membrane between the placenta and the uterine wall) exists in all these more simple forms of placentation; in the diffuse form it is the whole mucous surface; in the cotyledonary it is the "cups"; in the zonular, the mucous membrane with its laminar outgrowths; so that it follows that the large granular cells of the decidua serotina of the human uterus are no other than the modified cells of the crypts. 6. That in the zonular variety there are indications of the commencement of a sinus system in the maternal placenta.

As to the general morphology of the placenta, Prof. Turner remarked that mammalia were divided into two great groups, the *non-deciduata* and the *deciduata*; in the former (represented by the pig, mare, and cetaceans) no portion of the maternal tissues comes away at birth, while in the latter the maternal mucosa is more or less wholly detached (as in carnivora, quadrumana, and man). The usual definition of a deciduate placenta was that in which *vascular* maternal structures were brought away. Such a definition was too limited, and the term should be extended to include all those animals in which *any* part of the maternal structures was shed; for there are definite grades of deciduation, and Prof. Turner has recently found abundance of the epithelial lining of the cotyledonary crypts on the shed membranes of lambs and calves, showing that the ruminants should properly be classed as deciduata, and not among the non-deciduata. Then there are differences in the true deciduata themselves—e.g., in the cat the shedding is almost as complete as in the human female, the whole or great part of the mucous membrane in the placental zone coming away.

Lastly, as to the general physiology of the subject, the fœtus must be regarded as a parasite living on the juices of the mother. Doubtless in some animals the utricular glands play an important part in the nutrition of the fœtus; but in the seal and carnivora their epithelium is degenerated; and in the human female these glands disappear at the third or fourth month of pregnancy. The process of nutrition is then chiefly carried on by the new-formed crypts, which have all the characters and structures of glands, being lined by an epithelium and highly vascular, as is well seen in the diffused, cotyledonary, and zonular placenta. Harvey described a secretion in the cotyledons of ruminants which he termed "uterine milk," the product of the crypts in these structures. There are certain difficulties to be met with in applying these conclusions to the placentation of the higher mammalia, but the consideration of these Professor Turner said he would leave to another occasion.

The lectures were abundantly illustrated by several excellent specimens and histological preparations; and Professor Turner's lucid descriptions were aided by a series of well-executed diagrams.

Obituary.

J. F. CLARKE, M.R.C.S.

Those of our readers, and they are now few and far between, who can remember the establishment of The Lancet under the late Mr. Wakley, and its early career, will naturally associate therewith the name of the man whose death we have now to record. Mr. Clarke was probably one of the best known medical journalists in London. He commenced work for The Lancet (on the recommendation of Liston, who had a warm regard for him) shortly after its establishment, and was an eminently useful member of the staff for many years. For his line and mode of action were in consonance with the tone and feeling of the time some forty years ago, when close corporations existed, abuses abounded, and active purgations were sorely needed in our profession. Mr. Clarke was physically as well as mentally active. He was ingenious, too, in carrying out for himself ways and means of obtaining information, if that information were not procurable through the ordinary channels. Having passed through, seen, and observed closely several phases or turning points of the profession and their representatives, he had a fund of anecdote possessed probably by no other man of his own cloth in London, and his jokes were mostly good, and sometimes pungent. He was, in fact, a peripatetic encyclopædia of the past generation of doctors, commencing at a time when private schools of medicine flourished, and the Apothecaries' Society reigned supreme. He took his first diploma in 1837, and practised in Gerrard-street for many years, where he died on the 6th of July last.

JAMES BRYDGES SAYERS.

Frequenters of the Royal Dublin Society house will miss henceforth a familiar face. "Old Doctor Sayers," whose marked features and bent form have for more than twenty-five years been so well known at all the meetings of the Society, will appear there no more. He died at the advanced age of eighty-three on April 20th. He deserves, however, somewhat more than this passing mention. His family, which originally bore the name of Brydges, were of English origin. The name of Sayers was assumed with a property bequeathed with that condition.

James Brydges Sayers was born in the year 1792 in Limerick, near which place his father owned some property. He early showed an unusual capacity for knowledge, so that he became at the age of fourteen a student at the University of Edinburgh. During the following ten years he studied not only there, but in London and Dublin, and from all three cities he obtained diplomas and certificates in medicine, surgery, and midwifery. At the end of this period he appears to have had some intention of visiting Italy, in order to study at Padua and elsewhere the practice of the Italian schools of medicine and surgery; but at this time his elder brother, William Brydges Sayers, who was in extensive practice as a physician in Limerick, died, and James was summoned home to take his place. He continued to practise there for nearly thirty years, during which time he earned the affectionate regard of many whose lives he was the means of prolonging and whose sufferings he alleviated. About the year 1846 his health began to fail, and in 1848 he finally retired from practice, and removed to Dublin.

During all his active life as a physician, and even before, when only a student, Dr. Sayers had taken a deep interest in scientific pursuits, for his attainments in which he earned the respect of many whose names are now deservedly eminent in the world of science. His removal to Dublin enabled him to indulge his tastes more fully in the congenial atmosphere of the Royal Irish Academy and the Royal Dublin Society, of which last he was, as we have said, a prominent member.

Medical News.

Royal College of Surgeons of England.—The following gentlemen passed the Primary Examination in Anatomy and Physiology at meetings of the Court of Examiners on Monday, Tuesday, and Wednesday last:—

I. B. Noble and I. H. Callender, Newcastle-on-Tyne; F. Le M. Grosett, Toronto and Edinburgh; K. R. Kirtikar, University Coll. and Bombay; J. Peake, Glasgow; W. E. Margetson, Leeds; F. J. Spranger, G. F. Harris, and C. Winterbottom, St. George's Hospital; C. E. Shelly, Cambridge; A. R. M'Dougall, Edinburgh; W. Rhodes, Birmingham; F. F. Folkes, J. E. Pilkington, and J. Newton, Manchester; E. L. M'Ardle, R. Jones, W. Huey, and R. F. Owen, Liverpool; J. A. Irwin, L. R. Wilkin, and W. F. Jones, Dublin; R. Edmunds, E. S. Bontein, W. T. Jackman, J. S. Lambert, T. W. Fagg, W. M. Burgess, R. Lyddon, T. V. Nicoll, A. G. P. Gipps, W. Kay, F. A. Trevan, D. A. Sugden, A. S. Bradford, F. C. Craddock, A. G. Bernard, and J. Rhys, St. Bartholomew's Hospital; A. A. Wolff, St. Thomas's Hosp.; H. W. J. Liebstein, L. M. B. Jones, J. A. Masters, A. F. Stevens, and J. F. Dell, Guy's Hospital; R. T. Richardson, London Hospital; G. S. Robertson, Westminster; J. V. Continho, Bombay and University College; C. C. Jewell, C. C. Claremont, J. W. Bond, W. Gristock, and T. B. Green, University College Hospital; R. W. Collett, St. George's and Westminster Hospitals; H. C. Jee, Birmingham and Guy's Hospital; J. C. Gardner, Newcastle and University College; W. Pratt, Aberdeen; C. F. Goode, St. Mary's Hospital.

For the Pass Examination for the Membership of the College, which commenced on the 16th, there are over 170 candidates.

Apothecaries' Hall. — The following gentlemen passed their examination in the Science and Practice of Medicine and received certificates to practise on July 8th :—

Batterbury, Richard Legg, Haverstock-hill.
Blake, Andrew Henry, Castle-street, Berners-street.
Blake, Henry, Bedford.
Burton, Harry, Greenheys, Manchester.
Cooper, John Neild, Hyde, near Manchester.
Jones, Cyril Lloyd, Blackfriars-road.

The following gentleman passed the Primary Professional Examination on the same day :—

Inman, Robert Edward, London Hospital.

A **fatal** case of heat apoplexy, in a boy aged ten years, occurred last week at Upton.

John Reid, Esq., R.N., Largan Dunoon, has been placed on the Commission of the Peace for the county of Argyll.

Recent advices from Constantinople state that vessels arriving there from Syrian ports are now required to perform ten days' quarantine in the Dardanelles.

A **warder** in Greenock Lunatic Asylum has been charged with causing the death of a lunatic by throwing him down and kicking him. The insane patient was violent and first attacked the warder.

Dr. Samuel Rooth, of Dronfield, has been awarded by the Local Government Board a gratuity of £18 10s. for efficient vaccination in his district (Dronfield District of the hesterfield Union). This is the third time in succession that he has received it.

Presentation.—On the 6th inst., at Southport, near Liverpool, Mr. George Coombe, having fulfilled the period of his engagement as house-surgeon of the infirmary of that town, received from the governors of the institution a very handsome recognition of the services he had rendered. The first gift was a copy of a resolution of the Board of Governors, embodying a very warm expression of their thanks, beautifully illuminated on vellum; the second gift was a chronograph watch of the value of 40 guineas; and lastly, a purse containing £100.

Bequests, &c., to Medical Charities.—Miss Julia Ann Scott Webb, of Cadogen-place, bequeathed £5000 each (less duty) to the Metropolitan Convalescent Institution, Walton-on-Thames, and the Royal Hospital for Incurables, Putney. The Brighton and Hove Dispensary has received £5000 under the will of Mr. John Paine. The Hospital for Sick Children, Great Ormond-street, has received £1000 anonymously for the support of one cot in perpetuity in the new hospital. Mr. Peter Hardy bequeathed £1000 to the Worcester Infirmary, and £500 to the Worcester Dispensary. Mr. Wm. Henry Gore Langton, of Prince's-gate, Hyde-park, bequeathed £500 each to the Bristol Royal Infirmary and the Bristol General Hospital.

Medical Appointments.

Archer, E. G., M.R.C.S.E., has been appointed Medical Officer to the Ancient Order of Foresters, Diss, vice Button, resigned.

Barker, W. L., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer to the Convict Prison, Chatham, vice Burns, transferred.

Bell, J. H., M.D., M.R.C.S.E., has been appointed a Medical Officer to the Bradford, Yorkshire, Infirmary and Dispensary.

Betts, N. P., M.R.C.S.E., has been appointed Certifying Factory Surgeon for the District of Ashby-de-la-Zouch, vice Dicken, deceased.

Butler, E. Fitz Garret, L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer and Public Vaccinator for the Boston District and the Workhouse of the Boston Union, vice Radley, resigned.

Cobbold, C. S. W., M.D., L.R.C.P.Ed., M.R.C.S.E., has been appointed Assistant Medical Officer at the Metropolitan Asylums District Asylum for Lunatics, Leavesden.

Crawford, J., M.D., C.M., has been appointed Medical Officer for the Manningham District of the Bradford Union, Yorkshire, vice Sugden, deceased.

Davies, J., M.D., has been appointed Medical Officer and Public Vaccinator for the Ebbw-vale District of the Bedwellty Union, vice Brewer, resigned.

Drapes, J. B., M.B., C.M., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Keadue Dispensary District of the Boyle Union, Co. Roscommon, vice Smith, appointed to the Durrow Dispensary District of the Abbeyleix Union, Queen's County.

Dudley, J. G., M.D., has been elected a Consulting Physician to the North London Consumption Hospital.

Duncan, A., M.B., M.R.C.S.E., has been appointed Medical Registrar to the Charing-cross Hospital, vice Creighton, resigned.

Godson, C., M.D, C.M., M.R.C.P.L., has been appointed Assistant Physician-Accoucheur to St. Bartholomew's Hospital.

Goyder, D., M.D., L.R.C.S.Ed., has been appointed a Medical Officer to the Bradford, Yorkshire, Infirmary and Dispensary.

Greenfield, W. S., M.D., M.R.C.P.L., has been appointed a Physician to the Royal Hospital for Diseases of the Chest, City-road, vice Donkin, resigned.

Gregory, G., M.D., L.R.C.P.L., M.R.C.S.E., has been reappointed Medical Officer of Health for the Westhoughton Urban Sanitary District: £30 per annum.

Harrison, H. B., M.R.C.S.E., has been appointed Second Assistant Medical Officer to the Metropolitan Asylum District Asylum for Imbeciles, Caterham.

Hayman, F. D., M.R.C.S.E., has been appointed Assistant House-Surgeon to the Metropolitan Free Hospital, Devonshire-square, vice Harrison, resigned.

Johnston, W. W., M.R.C.P., has been elected a Consulting Physician to the North London Consumption Hospital.

Leacroft, J. W., M.B., has been appointed a Public Vaccinator to the Alcester Union, vice Hiron, resigned.

Meade, H., M.R.C.S.E., has been reappointed a Medical Officer to the Bradford, Yorkshire, Infirmary and Dispensary, upon the expiration of his term of office under the rules.

Pettinger, Mr. G. W., has been appointed a Factory Surgeon for Manchester, vice Dr. Pettinger, who has resigned from ill-health.

Powell, J., M.R.C.S.E., has been appointed Medical Officer for the Penbryn District of the Newcastle-Emlyn Union, Carmarthenshire, vice Evans, deceased.

Rose, W., F.R.C.S.E., has been appointed an Honorary Surgeon to the Royal Free Hospital, vice Hill, deceased.

Ruckley, H. R., L.R.C.P.Ed., L.R.C.S.I., has been appointed Certifying Factory Surgeon for the District of High Wycombe, vice Bowstead.

Shone, W. J., M.R.C.S.E., has been appointed Certifying Factory Surgeon for the District of Great Marlow.

Smith, G., M.D., M.R.C.P.L., has been appointed a Physician to the Royal Hospital for Diseases of the Chest, City-road, vice Dobell, appointed a Consulting Physician.

Stafford, J. F., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer and Public Vaccinator for the No. 4, or Windlesham District of the Chertsey Union, Surrey, vice Kough, resigned.

Stone, V., F.R.C.S.Ed., L.R.C.P.Ed., has been appointed Medical Officer and Public Vaccinator for the Parish of Fettercairn, vice Stephen, resigned.

Williams, J., M.D., has been appointed Medical Officer to the Penrhyn Quarry Benefit Club and Hospital, vice Roberts, resigned.

Wilson, C. W., M.R.C.S.E., has been appointed a Surgeon to the Convalescent Society and Prudhoe Memorial Convalescent Home, Whitley, vice Forster, resigned.

Births, Marriages, and Deaths.

BIRTHS.

Berton.—On the 4th inst., at Sydenham, the wife of Edwin D. Berton, M.B., of a daughter.

Duckworth.—On the 10th inst., at Grafton-street, Piccadilly, the wife of Dyce Duckworth, M.D., of a son.

Glen.—On the 6th inst., at South-bank, Yorkshire, the wife of James Glen, M.D., of a son.

Hewlett.—On the 14th inst., the wife of John C. Hewlett, Esq., of The Ferns, Hornsey, and Cree Church-lane, Leadenhall-street, of a daughter.

Macfarlane.—On the 8th inst., at Walmer, Kilmarnock, N.B., the wife of Alex. W. Macfarlane, M.D., of a daughter.

Miller.—On the 9th inst., at Church-road, Upper Norwood, the wife of R. M. Miller, M.D., of a daughter.

Sutcliffe.—On the 5th inst., at Denmark-hill, the wife of John Sutcliffe, M.R.C.S.E., of a daughter.

MARRIAGES.

Fletcher—Portchett.—On the 7th inst., at St. John's, Tottenham, John Corbet Fletcher, M.D., to Martha Parker, daughter of J. S. Portchett, Esq.

Phillips—Anderson.—On the 7th inst., at Edinburgh, Robert Edward Phillips, B.A., M.B., of Bromley, Kent, eldest son of the late Edward Phillips, M.D., to Christian Gibson, second daughter of Major-General Anderson, C.B., late Royal Artillery.

DEATHS.

Bell.—On the 24th ult., at The Scores, St. Andrews, Oswald H. Bell, M.D., aged 38.

Birt.—On the 10th inst., at Harcourt-terrace, West Brompton, Hugh Birt, F.R.C.S.E., aged 61.

Burnett.—On the 4th inst., at Tullow, Co. Carlow, R. Burnett, L.K.Q.C.P.I., aged 67.

Crozier.—On the 9th inst., at Arundel-street, Strand, H. Acheson Crozier, M.R.C.S.E., aged 74.

Hopkinson.—On the 24th ult., at St. Martin's, Stamford, Wm. Lander Hopkinson, M.D., aged 77.

Menzies.—On the 7th inst., at Westbourne-park-road, Duncan Menzies, M.R.C.P.L., Deputy Inspector-General Army, aged 72.

Mitchell.—On the 2nd inst., at Ladykirk House, Monkton, Ayrshire, Alex. Mitchell, M.D., R.N.

Moir.—On the 8th inst., at Dicconson-street, Wigan, Lancashire, Julie Marie, the dearly beloved wife of G. C. Algernon Moir, M.R.C.S.E., L.R.C.P.L., in her 25th year.

Olive.—On the 4th inst., at Buxted, Sussex, Edward Olive, M.R.C.S.E., aged 37.

Taplin.—On the 10th inst., at Lansdowne House, Coventry-road, Smallheath, Birmingham, Edith, the infant daughter of J. F. Taplin, M.D., aged 13 months.

Workman.—On the 29th ult., at Basingstoke, Geo. Workman, M.R.C.S.E., aged 71.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*]

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Report from the Court of Examiners of the Number of Candidates who have presented themselves for the Primary and Pass Examinations for the Diploma of Member of the College during the Collegiate Year 1874–75, showing the number who have passed and have been rejected from each Medical School during that period.

PRIMARY EXAMINATIONS.—1874–75.

20th May, 1875. F. Le Gros Clark, President.

Notes, Short Comments, and Answers to Correspondents.

Hospitalism.

The *Continental Herald* states that Dr. Lefort, surgeon of the Beaujon Hospital, has just placed in the grounds of the institution a vast tent, to which he has removed all his patients. The object of Dr. Lefort is to try whether the open-air system would not affect favourably the amount of mortality following surgical operations, and thus help to solve the question of hospital ventilation.

M. Tholozan's Views on Cholera.

M. Tholozan is physician to the Shah of Persia, and has been so for many years. He may be considered to have enjoyed special opportunities of studying diseases of Eastern origin. His opinions, therefore, on cholera are entitled to particular attention. Being at the present time in Paris, M. Tholozan has laid his views before the Academy of Medicine, and we here offer an abstract of them. The starting-point of the epidemics of 1831, '47, '52, '56, and '65 had in former communications been settled by the author, he having shown that most of the epidemics which have been observed in Europe for the last thirty years have not been imported from India, but have arisen from the germs left by preceding epidemics. He wished to ground his opinion upon facts alone, especially as to the nature of the original manifestations of cholera, and the manner in which it has spread. M. Tholozan endeavours to prove that in India as well as Europe the epidemics of one period spring from incompletely extinguished former epidemics. Cholera reigns in Europe in the same manner as on the banks of the Ganges. It incontestably travelled first from Asia to Europe; but it is equally sure that for the last sixty years it has settled amongst us, continues so, lies dormant, and sometimes breaks out, just as happens in India. Those who think that every cholera epidemic in Europe is imported from India are in error, no facts supporting the theory. The truth is, according to the author, that the scourge has a wonderful power of spreading, and exhibits variable intensity and symptoms. But although the effects, the manifestations, and the contagious properties present modifications, although the danger may increase or diminish, the morbid entity remains the same, and those who make a distinction between Asiatic cholera and the sporadic form of the disease (cholera nostras) are grievously mistaken. M. Tholozan is a supporter of quarantine and sanitary restrictions, on account of certain advantageous results which have accrued from them.

The letter of *Mr. Cripps Lawrence* shall be kept in mind.

Swimming as a Convivial Entertainment.

To the Editor of The Lancet.

Sir,—If feats in swimming are to become matters of competitive examination, I think some rules should be issued for the performances.

The great danger the swimmer is exposed to is the benumbing effect of cold, and the man who can best endure it is the man capable of remaining uninjured the longest period in the water; but a swimmer who is assisted by "goes" of brandy while he is in the water does not prove how long he can remain in the water trusting *only* to his own strength, but rather what effect spirits have in enabling a man to resist cold. There are plenty of men in England who would think little of swimming twenty miles with the tide running four knots in their favour; but I do not think there are many who could do it comfortably or without suffering if unassisted by refreshments or stimulant of some kind. An experiment might be tried in the interests of science by testing a man's endurance of cold in the water under the effect of different diet. Twenty miles on a teetotal system *versus* the same distance supported by fermented drinks would form a splendid competitive examination, and draw an enormous concourse of publicans and Permissive Bill people as spectators; but of course, so far as swimming pure and simple goes, the trial would prove nothing at all. As a general rule, shipwrecked people or persons falling overboard, or those who jump after them to rescue them, have no kind friends to administer stimulants while boats are being lowered to pick them up. At any swimming competition I should say nothing should be taken when once the swimmer has entered the water until he comes out again. It would be rather curious to ascertain if the loss of heat would be greatest in a long swim if the man before commencing took—first, brandy; secondly, tea; or thirdly, merely rubbed his body well with oil.

Yours &c.,

July, 1875. A Porpoise.

W. M. B.—Under the circumstances mentioned, it would be best to apply at the Fever Hospital. It is not desirable that the general hospitals should admit such cases, unless they are provided with special wards completely detached.

Dr. T. J. Denton.—Hypophosphite of calcium.

Leprosy in Bombay.

A correspondent of the *Standard* writes from Bombay as follows:—

> "There are more than 200 lepers in Bombay; but I little expected to see Europeans among them, and to learn that it was by no means an uncommon thing. One of these unfortunates had been a clerk, one a sailor, and one a railway *employé*. The whole subject is one to which I desire to call special attention. Some days afterwards I went over the Jamsejee Dharmsála, or almshouse, where the great mass of the lepers congregate. Here I saw nearly 200 persons—men, women, and children—suffering from this frightful disease, and occupying rooms which, when vacated by them, are taken by other persons free from the disease. Is it any wonder that under such circumstances the disease should spread? I had the advantage of going over the place with Dr. Vandyke Carter, the greatest living authority on the malady, and his decided opinion is that the only way to stamp it out is to seclude the sufferers. In face of this, how is it that Government allows the lepers to live in a public almshouse, open to all comers, and to mix daily with the crowds that throng the streets of Bombay? No wonder that our unfortunate fellow-countrymen are among the victims of such a system. I may add that some beggarly economy of the Calcutta people bids fair to put a stop to Dr. Carter's researches. He is a man wholly devoted to the study of how to relieve mankind of this scourge. He has visited other countries to prosecute his inquiries. He has undertaken the loathsome task—made glorious indeed by the spirit that animates him—of dissecting the bodies of those who die of the disease, and has by the microscope made important discoveries. One would have thought that gold could not purchase devotion to such a cause, and is it all to be thrown away in order to save a small sum which will probably be immediately wasted in building some useless outhouse?"

Late Messages to Doctors.

SOME patients are peculiarly orderly in regard to their habit of sending for the doctor. They seem always to be taken ill at the proper time, and to send a message that can be considered before their medical officer leaves his house in the morning. And some patients are just the reverse. Their ailments happen at the most inconvenient hours, or rather their messages arrive then—just when the doctor is going to dine, or just after he has come in from a long round, in the course of which he passed the unmethodical patient's door. The Forfarshire Medical Association has properly resolved to try the effect of a remedy for this unmethodical style of patient. According to the report of the proceedings at the seventeenth annual meeting, the resolution unanimously adopted at the last year's meeting, "that all visits sent for at 10 A.M. and requiring to be attended to the same day, should be charged at an extra rate," was again confirmed, and ordered to be advertised in all the papers published in the county. We commend this resolution to the attention of other Societies.

Dr. Ramskill's lecture shall be published.

The New Fever Department of the Sussex County Hospital.

To the Editor of THE LANCET.

SIR,—If you had been acquainted with all the circumstances attending the proposed erection of a new building for infectious disorders in connexion with the Sussex County Hospital, and respecting which there has been a good deal of misrepresentation in the town, I am very much mistaken if you would not have come to a different conclusion as to the desirability of transferring the new building to a site beyond the boundaries of the town rather than placing it where it is now proposed, inside the hospital grounds, and within a few yards of the main building. The fact is that this addition to the hospital originated, not with the fever department, but with the difficulty of knowing what do with our erysipelas cases. Everybody acquainted with hospital practice knows how very important it is that all cases of erysipelas should be immediately removed from the surgical wards, and kept separate from the rest of the patients, with a separate staff of nurses, dressers, &c. &c. This accommodation the Sussex County Hospital does not at present possess, and for the want of it we have not unfrequently been put to very great inconvenience. It was thought accordingly by the medical staff that Miss Poore's beneficent donation could not be better spent than in providing a building for the above object, and, as the funds were sufficient, that it would conduce still further to the convenience and security of the hospital and neighbourhood if the fever wards were also removed, and made part of the new and detached building. Hence the origin of the proposed so-called new fever hospital, of which so much has been said. All general hospitals must have some amount of accommodation for fever and other infectious disorders, for cases which not unfrequently originate within the institution, as well as for the use of the subscribers. Besides, cases of fever are constantly occurring which, either from the weakness of the patients or the unwillingness of the parents and friends, do not admit of being sent long distances out of town. As we do not intend to increase the accommodation for infectious disorders by a single bed, and the new building will enable us to take extra precautions to prevent the spread of infection, both as regards the institution itself and the neighbourhood, it puzzles me to know what possible objection there can be to it.

As regards extra-mural fever hospitals, my impression is, though all medical men readily admit the great importance of isolation in all infectious disorders, that under present circumstances little real good would be derived from them. Setting aside the difficulty which would very often be experienced in getting a suitable site for such institutions, which is now the case with the proposed fever hospital for the metropolis, the cost of the buildings and their subsequent maintenance would be very considerable, and, after all, they would be very little used. People, as a rule, have a great objection to sending their children and relations a long distance into the country. Such institutions might certainly come into use during serious and extensive epidemics; but as regards Brighton there are fever wards at the infirmary which might be made available on such occasions. Granted that one source of infection, both as regards the atmosphere and drains, would be removed from the town centres, yet scores of others would still remain from the private houses where illness existed, so that but very infinitesimal results would be produced. Besides, there is no reason why the evacuations of hospital fever patients should be allowed to go into the street drains at all. They might be disposed of in some other way, or they might be disinfected before passing into the drains, and I hope that some such precautions will be taken in the new fever department of the Sussex County Hospital. I admit that if Government should ever give local authorities the power of enforcing isolation in infectious diseases, extra-mural fever hospitals would become a necessary adjunct to all large towns, and that under such circumstances great good would doubtless result from them. But I fear that the public at present are very far from being willing to submit to any such useful legislation.

I am, Sir, your obedient servant,

WILLIAM KEBBELL, M.D.,

July 2nd, 1875. Senior Physician to the Sussex County Hospital.

Mushroom Poisoning.

THE house-surgeons of the Charité Hospital at Lyons partook a short time ago of a piece of pastry (vol-au-vent), which, among other ingredients, contains mushrooms. Two of the young gentlemen ate of these mushrooms—one moderately, the other more freely. Severe symptoms of poisoning soon occurred; they were slight with one of them, but so severe with the one who had eaten freely that he had a narrow escape of his life.

German Medical Literature.

To the Editor of THE LANCET.

SIR,—If "Fatherland" likes to avail himself of any aid I can give him, it shall willingly be afforded him, as I long lived in Germany.

Yours &c.,

Ipswich, July 9th, 1875. HENRY P. DRUMMOND, M.D.

Alcohol in Naval Hospitals.

IT is stated that the Admiralty has decided that patients in the naval hospitals who may be total abstainers, and do not consume the amount of beer or wine prescribed for them, shall in future be paid the value of such liquors. This arrangement, if really contemplated, whilst probably owing its origin to a philanthropic desire to encourage temperance in the navy, appears to us open to question with regard to its consistency. The stimulants are either needful to the patients or they are not. If the former, money cannot properly be substituted for them; if not necessary, they should not be ordered, and a money equivalent is out of the question.

Mr. R. Harrington.—We regret we cannot oblige our correspondent.

Section-Cutters.

To the Editor of THE LANCET.

SIR,—I regret that my description of my modification of the freezing section-cutter was in your hands before I saw Mr. Lawson Tait's valuable article on the subject in the last number of the *Journal of Anatomy and Physiology*. In your issue of the 3rd inst. he expresses an opinion that the great objection to my instrument is the constant attention it requires, and the difficulty this will occasion to observers whose time is interrupted. It seems to me that his instrument requires more constant attention, and attention of a much more skilled kind, during the process of freezing than does mine, and that the advantage of keeping the tissue frozen for a great length of time is very slight. By reducing the outflow from my instrument after the freezing is complete, it can easily be kept in good condition for a considerable period; and it seems to me that as the great advantage of the process consists in the facility it affords for completing the cutting of sections at once, little is to be gained by the prolongation of the time during which the object is in a fit condition for the purpose. Having once got everything working, as many sections can be cut in a few minutes as can be desired, and, once cut, they can be kept in suitable solutions for any time. An immense saving of trouble is effected by the avoidance of the fine division of the ice which Mr. Tait advocates. A coarse pounding suffices for use with my process, as a large vessel can be used to contain it. As to fixing the instrument to the table or keeping it free, of course this is a detail which each worker can have arranged to suit himself. I may mention that I am having an instrument constructed almost entirely of vulcanite, which I hope will give great lightness, and do away with the necessity of cork or other coverings to keep out heat.

I am, Sir, yours &c.,

Glasgow, July, 1875. WM. JAS. FLEMING.

F. W. N. (Reading) should consult Dr. Schultze's recently published pamphlet (Heidelberg: Winter) on the Results of the Cold-water Treatment in Abdominal Typhus. The exposition is clear and impartial. Out of 648 cases in the Heidelberg Infirmary between the years 1864—73, Dr. Schultze found that in nearly all the treatment was favourable in its effect on the nervous system; that it was contra-indicated in those where neuralgia or hyperæsthesia existed; that it did good in lung complications; but that in intestinal hæmorrhages it was mischievous.

Mr. Schindler, (Kennington.)—The MS. shall have our early attention. We should be glad, however, to have an opportunity of inspecting the work in question.

American Degrees.

To the Editor of THE LANCET.

SIR,—In your journal of June 5th, page 811, I notice what may be the very just censure of a medical (?) man claiming to possess an American qualification. But will you kindly inform me what is meant by the "wretched character of that (degree) of Pennsylvania"?

There are in Philadelphia two medical schools, known respectively as the "Jefferson" and the "University of Pennsylvania," offering advantages for acquiring a first-class medical education, nearly equal to any school in the world, the honourable professors of which, I beg leave to say, are highly respected in England as well as in America.

Some time since an unprincipled charlatan advertised to sell diplomas of the "University of Philadelphia," and some unfortunate Englishmen and others were induced to buy them. No regular physician or surgeon has ever been connected with this so-called "University of Philadelphia," which you must have confounded with the regular "University of Pennsylvania," *located* at Philadelphia, thereby creating a prejudice against institutions worthily enjoying great honour and confidence.

It is but justice to the medical profession of the United States to assure you that it is quite impossible to purchase or otherwise fraudulently obtain the degree of M.D. from any regular medical school in the State of Pennsylvania, or any other State of the American Union. The English medical profession is certainly too much indebted to American medical enterprise in pharmacy, medicine, and surgery to condemn in such a sweeping term the very centre of American medical education.

I am, Sir, yours &c.,

Ventnor, I.W., June 19th, 1875. NOT AN AMERICAN GRADUATE.

⁂ We do not confound the University of Philadelphia with that of Pennsylvania, though perhaps our expression was open to misunderstanding. Our correspondent does not overstate the respectability of the true University of Pennsylvania, though he passes too lightly over the case and the crimes of the "University of Philadelphia," whatever that may mean, and over the evil of innumerable degree- and diploma-granting bodies in the States.—ED. L.

The Professorship at the College of Surgeons.

A PRINTER'S error occurred in our article last week on the recent changes in the College of Surgeons. It is made to appear that Mr. Flower will be associated in the ensuing year with Mr. Turner, of Edinburgh. It should be with Mr. Parker (in the Chair of Comparative Anatomy and Physiology).

Mr. T. W. Watkins (Leipzig) is thanked. We are afraid we cannot avail ourselves of the offer.

PROFESSIONAL REMUNERATION.

AT a time when there is a strong feeling among the consulting members of the profession that the fee of a guinea (representing so much less now than formerly) should be increased, it is interesting to learn that veterinary surgeons are raising their scale of charges. We believe we are right in stating that several of the leading veterinary surgeons have recently increased the fee for examining a horse from half a guinea to a guinea. The initiation taken by Mr. Mavor will, doubtless, be accepted with acclamation by the whole veterinary profession, from the gentleman who examines a race-horse, whose value is reckoned by thousands of pounds, down to the village farrier, who drenches the horses, and their humble congener, the mule. Is it not full time that the position of the hard-worked and ill-paid general practitioner should be ameliorated?

Alpha.—No.

INCONTINENCE OF URINE.

To the Editor of THE LANCET.

SIR,—One of your correspondents in THE LANCET of Jan. 23rd asks for information as to the treatment of incontinence of urine, and in your issue of the 30th of the same month half a dozen responses are made. A little more careful perusal of the admirably conducted department of THE LANCET devoted to "Notes, Short Comments, and Answers to Correspondents," would have caused some consideration of the note on "Ritual Circumcision" in the issue of Jan. 9th, where Dr. A. Mayer says, "It is also a known fact that circumcision cures enuresis nocturna when caused by a prepuce with a narrow opening." The fact that of the six respondents, two recommend belladonna, and the other four as many different modes of managing the difficulty, would show that the *cause* had not been looked after. My own experience, which has been extensive, has convinced me that enuresis in youth and in adult life is frequently due to a contraction either of the preputial orifice or of the meatus urinarius, and that sedatives and narcotics may palliate, but do not cure. Circumcision or division of the preputial orifice, when the prepuce alone is at fault, will give prompt and permanent relief; when this does *not* give relief, the meatus urinarius will often be found constricted, and a relief of this constriction will give the desired result. Let me cite a case or two.

G. H——, a lad of ten, had been troubled with nocturnal incontinence two or three times in the night and also often during the day for two years. Belladonna in quarter-grain doses relieved him temporarily, but on cessation of the drug would return. He was found to have redundant prepuce with contracted orifice. I circumcised him in October, 1874, found some adherence of prepuce to glans, and also a very small meatus urinarius. This I enlarged to 22 Fr. From date of operation he was completely relieved for four weeks, when the difficulty reappeared. I then made another examination, and found the meatus recontracted to 16 Fr. I then redivided it to 24 Fr. Since then he has had not the slightest trouble, and, furthermore, has been in better health than for several years.

I have just received a letter from Dr. C. H. Mastin, of Mobile, La., which I desire to add to this statement, and let your correspondents judge of its value. Dr. M. is one of the leading surgeons of the South-West: "Following I furnish you the brief notes of a case which I fancy will interest you, as it bears so strongly on your theory of reflex irritation, which I, for one, believe is ere long destined to become a fixed surgical truth. On the 29th of last month (November, 1874) I was requested to see a little boy, eighteen months old, the son of a gentleman of this city. The child was very delicate, pale, fretful, no appetite, languid, complained of pain whenever he passed his water. He was wakeful at night, and in the nightly habit of wetting his bed during sleep. From the description given me I was led to believe that the child had stone. Upon examination, however, I failed to discover stone, but found that the child had an elongated prepuce, the orifice of which was very small, congenitally contracted, so small, indeed, that there was difficulty in passing an ordinary silver probe. I was satisfied that the case was one of reflex irritation from narrowing of the preputial orifice. The physician with whom I saw the case in consultation laughed at this diagnosis; but, inasmuch as there was an evident obstruction to urination, consented to a free division of the preputial orifice. The results of this simple operation proved the correctness of your views and of my diagnosis established thereon. The very next day my little patient was decidedly improved, ate well, slept quietly, had no incontinence of urine, and up to to-day (one month from the date of operation) he has remained perfectly well in this respect, and his father says he has gained eight to ten pounds of flesh, and is in better health than ever before."

I remain, Sir, yours faithfully,
New York, June 9th, 1875. F. N. OTIS, M.D.

A Constant Reader has forgotten to authenticate his communication with his card. If he will do so we shall be happy to refer to the matter. Any further information obtainable about the outbreak should be forwarded without delay.

Dr. R. H. Pierson, (Dresden.)—We have not as yet noticed the meeting, but shall be glad to receive a very short report of the proceedings this year, if of interest to British practitioners. The other matter has not been forgotten.

DOUBLE DISLOCATION OF THE SHOULDER.

To the Editor of THE LANCET.

SIR,—A rather unusual case was admitted into the Birkenhead Borough Hospital some weeks since, under the care of Dr. Spratly. I was called into the surgery to see a patient, and found on examination that he had sustained dislocation of both shoulders into the axillæ. It appeared that the man, who is a carpenter, while working upon some scaffolding, lost his footing and fell, striking the ground with both elbows at the same time, and thus causing the injury. I easily reduced the dislocation by means of my heel in the axillæ, and the patient has since left the hospital cured.

I am, Sir, your obedient servant,
D. CHARLES DAVIDSON,
Senior House-Surgeon, Birkenhead Borough Hospital.
Birkenhead, July 3rd, 1875.

CHEMISTS BEWARE!

A CHEMIST, Mr. Adam Lawton, of Price's-end, Dudley, has just been fined £20 for practising and acting as an apothecary. It would be difficult to find a chemist nowadays who does not do so. If the Apothecaries' Society were frequently to take such action as that pursued so successfully against Mr. Lawton, they would help chemists to keep themselves within reasonable bounds, and to leave the practice of medicine and surgery to those duly qualified for it.

Mr. S. Jacobs, (Birmingham.)—We would advise our correspondent to speak to a medical man in his own neighbourhood.

THE APOTHECARIES' SOCIETY.

To the Editor of THE LANCET.

SIR,—As regards the annual dinner, termed "herbarising," given to the members of the Apothecaries' Society once a year, and paid for principally, if not entirely, as I understand, by the proprietors of the first-class stock, the real grievance of the business lies, I apprehend, in the fact that of late years the dividends on this stock have considerably decreased from their former proportion, and consequently, while the expenses of the entertainment remain the same, or may even have augmented in these dear times, these latter, therefore, are certain to fall heavily on the purses of some of the gentlemen who have for the time being to "pay the piper," and who probably, having looked to this investment as an additional source of income, find possibly their whole dividend for the current year swamped. On former occasions this was not so, and a handsome balance would still be left. I would ask the question of some member better informed than myself, whether there does not exist a bye-law to the effect that the expense of the herbarising dinner shall not exceed 2*s*. 6*d*. per head? Now, should the members (on whose unhappy shoulders it falls to provide these annual dinners) elect to abide by this arrangement, I imagine the number of guests would not be overwhelming, and, as Paddy said, "the coort was cleared." The law, if this be so, would be carried out in its integrity, and an onerous tax removed from that section of the proprietary who, it is well known, can ill-afford the outlay involved in these annual banquets.

I remain, Sir, yours &c.,
London, July 10th, 1875. ANOTHER MEMBER OF THE SECOND CLASS.

To the Editor of THE LANCET.

SIR,—I have made up my mind to follow the example of Mr. Bury (see last week's LANCET)—viz., in the interest of the stewards of the "general herbarising dinner," to decline the invitation sent me by the Master and Wardens. If those who wish to put an end to these unnecessary feasts will do the same, or if they have accepted they will withdraw their names, they will give a valuable practical hint to the Master and Wardens, and save the pockets of the stewards.

I am, Sir, yours faithfully,
July, 1875. M. S. A.

Registered Practitioner.—1. Immediately after the erasure of a name or names from the Medical Register for infamous conduct in a professional respect, the Registrar of the Medical Council sends notice thereof to the nineteen licensing bodies, to which notice is added a copy of the following resolution:—"That the Council recommend that any person whose name has been once removed from the Register shall not be admitted to examination for any new qualification without the consent of the General Medical Council."—2. The General Medical Council only, sitting in conclave, can undertake so important and serious a matter as the removal of a name from the Medical Register, which precludes the practitioner from afterwards legally following his profession.

POOR-LAW RELIEF.

To the Editor of THE LANCET.

SIR,—I shall feel obliged by advice from some of your readers on the following matter, perhaps trivial, but, to my mind, important.

W. is parish doctor in this district. I am a duly registered practitioner in the same parish. R. is a patient in my club, totally disabled, and with no means of support, he not being entitled to sick pay from the said club. At his request I furnish him with a certificate, stating that he is incapable of doing any work. On his presenting it to the relieving officer, he is told that my certificate is of no legal effect, and that unless he engages the services of W. for the future, he may "lie there and clog and die" before he shall receive parish relief.

My object, Sir, in writing is to ascertain whether or no the relieving officer can ignore my certificate, and compel the man R. to be attended by W., and give up his own medical man, before granting him assistance.

I am, Sir, yours &c.,
July, 1875. JUSTICE.

Microscopist.—A good Hartnack with immersion lenses costs, we believe, some £12. An old Ross's quarter may sometimes be purchased second-hand for £1 or £2 (a new one costs £7 10*s*.), and with a high eye-piece will be nearly all that an ordinary practitioner requires, unless he is pursuing some special investigation, in which case we recommend the Hartnack. There would be no difficulty in making the adaptation our correspondent suggests.

THE VALUE OF BROMIDE OF POTASSIUM IN PUERPERAL CONVULSIONS.

To the Editor of THE LANCET.

SIR,—For some years past I have found the bromide of potassium so valuable in the treatment of puerperal convulsions that I feel justified in bringing it under the notice of your readers. It appears as useful when the fits have come on before labour as after, and I consider it of equal value whether albumen is present in the urine or not. I give fifteen grains in mint water every two hours, and I have observed an improvement after the third dose.

Yours faithfully,
Hurstpierpoint, July, 1875. M. MONCKTON.

Lucina, (York.)—Two distinguished Saxon physicians, one of whom holds high office in the University of Leipzig, have jointly produced a text-book for midwives which strikes us as well deserving translation. Its title is "Lehrbuch der Hebammenkunst"; its authors are Drs. Crede and Winckel; its publisher is Hirzel, of Leipzig; and its price is 4s. 6d. Sound judgment is shown, not only in stating clearly and succinctly what midwives ought to know, but also in withholding knowledge which can only tempt them to go beyond their sphere.

Major-General Shaw, (Portsoy, Banffshire.)—Our correspondent's communication is acknowledged with thanks.

MILITIA SURGEONS.

To the Editor of THE LANCET.

SIR,—As there were no signs of the publication of the new Militia Medical Regulations, the following question was put to Mr. Hardy by Dr. Lyon Playfair last night:—"Whether, if he was unable to fix a date for their issue, he would state if it was intended under them to retain the services of the militia surgeons with the same pay and allowances as at present, or to dispense with them altogether?" The answer is given in *The Times* of to-day, as follows:—"The Regulations relating to yeomanry and volunteers are actually settled; but difficulties have arisen with regard to the militia medical officers, through their being brought into contact with the brigade depôts. He hoped the regulations would be published at no distant date." By this it will be seen that the real pith of the question is not answered. Can they, or can they not, retain our services? If they can, it must not be with *less* pay and allowances, because we shall be liable to the same contingencies as at present—viz., forced absence from home at camp or training centre, and interference with private interests. If they cannot, they must be prepared to meet demands for compensation, and to find qualified men to take charge of the one hundred and thirty regiments during the annual training at camp or training centre; for no present militia surgeon will retain his commission for this one month's pay alone. There is no doubt it is a hard nut to crack for the War Office, and hence the delay in issuing these new Regulations. Your obedient servant,

July 14th, 1875. MILITIA SURGEON.

COMMUNICATIONS not noticed in the current number will receive attention in our issue of the ensuing week.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. G. Johnson, London; Mr. Berkeley Hill, London; Dr. Spencer, India; Mr. Morgan, London; Major-General Shaw; Dr. Henderson, London; Dr. B. Foster, Birmingham; Surgeon-Major Ringer, Oudh; Mr. Harrington, London; Mr. Maunder, London; Mr. Bullen, Kennington; Mr. Baker, London; Mr. Braden, Lewes; Dr. Lawson, London; Dr. Carter, Birmingham; Mr. Kershaw, London; Mr. Chapman, London; Dr. Duncan, London; Dr. Parkes, Chatham; Mr. Anderson, Newtown; Mr. Pettinger, Manchester; Mr. Arthur, Diss; Dr. Cane, Peterborough; Mr. Hastings, London; Dr. Rhind, Torquay; Mr. Bolton, Nenthead; Mr. Gramshaw, Walton-on-the-Naze; Dr. Reoch, Newcastle-on-Tyne; Dr. Worthington, Benson; Dr. Langley, London; Mr. Philp, Stirling; Dr. D. Duckworth, London; Messrs. Robertson and Scott, Edinburgh; Mr. Coombe, Southport; Messrs. A. and C. Black, Edinburgh; Mr. Markby, Tyfield; Mr. Lucas, Hitchin; Mr. Kerbey, London; Mrs. Harrison, Camden-road; Dr. Pierson, Dresden; Mr. Dixon, Manchester; Messrs. Medical Diary for the ensuing Week.

Monday, July 19.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M. each day, and at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.
ST. MARK'S HOSPITAL.—Operations, 9 A.M. and 2 P.M.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ST. PETER'S HOSPITAL.—3½ P.M. Expected Operations: Lithotomy; Subcutaneous Urethrotomy.

Tuesday, July 20.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 3 P.M.

Wednesday, July 21.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. MARY'S HOSPITAL.—Operations, 1½ P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.
ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.
KING'S COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at 1½ P.M.
GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.
LONDON HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2½ P.M.

Thursday, July 22.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

Friday, July 23.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
QUEKETT MICROSCOPICAL CLUB.—8 P.M.—Annual General Meeting.

Saturday, July 24.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NOTICE.

In consequence of THE LANCET being frequently detained by the Post Office when posted for places abroad *more than eight days after* publication, subscribers and others are reminded that such copies can be forwarded only as book packets, and *prepaid* as such.

TERMS OF SUBSCRIPTION TO THE LANCET.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year	£1 12 6	Six Months	£0 16 3

TO THE COLONIES AND INDIA.

One Year	£1 14 8

Post Office Orders in payment should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable to him at the Post Office, Charing-cross.

TERMS FOR ADVERTISING IN THE LANCET.

For 7 lines and under	£0 4 6	For half a page	£2 12 0

Clinical Lectures

ON THE

RECTUM AND ANUS IN THEIR RELATIONS TO UTERINE, OVARIAN, AND PERIMETRIC DISEASES.

By ROBERT BARNES, M.D.,

OBSTETRIC PHYSICIAN TO ST. GEORGE'S HOSPITAL;
EXAMINER IN OBSTETRICS TO THE ROYAL COLLEGE OF SURGEONS.

LECTURE IV.

Effects of Pregnancy and Labour; Incontinence of Fæces; Constipation; Obstruction; Effects of Displacements of the Uterus; Diagnosis of Rectal from Uterine Disease; General Paralysis; Retention of Fæces, its effects; Malignant Disease; Perimetritis; Ovarian Disease; Blood, Pus, Bones, Hairs, &c., in Fæces.

Although the uterus is not in such intimate relation to the rectum as it is to the bladder, it is still so close to it in position that disorder or distress referred to the rectum is an extremely frequent complication of uterine disease or displacement. The unity of the pelvic vascular system is such that engorgement or inflammation of the uterus cannot fail to cause increased afflux of blood and hæmostasis in the other pelvic organs. To this increased flow of blood, determined by inflammation or congestion of the uterus, there is necessarily added the mechanical effect of increased weight and bulk. Thus two conditions already combine to cause accumulation of blood in the hæmorrhoidal vessels. A third condition is rarely wanting long. This is displacement of the uterus. The prolapsus consequent upon increased weight of the uterus, and the relaxation of its supporting structures, brings a further aggravation of pressure to bear upon the rectum just above the anus, increasing the difficulty under which the hæmorrhoidal vessels labour in unloading themselves.

To these mechanical influences in producing local vascular stagnation other remote and secondary causes bring a contingent of trouble. The gradual impairment of digestion and other nutritive functions, the enforced inactivity, consequent on uterine disease, entail constipation and loss of sphincteric tone. Hence the disposition of the hæmorrhoidal vessels to dilate, to become varicose, and to favour the formation of piles and thrombi, is enforced in a variety of concurrent ways.

The foundation of rectal and anal distress is often laid in pregnancy. The active developmental nisus, bringing to the pelvic vessels a large quantity of blood, leads to distension, to venectasis, which does not always subside after labour. The dilatation of the vascular plexuses around the lower part of the vagina and vulva arising during pregnancy has been already described. A similar condition is found around the anus; during labour, the extreme compression to which this part is subjected may retard the circulation in the vessels for several hours, and then, during the final act of expulsion, the tissues in which the vessels are embedded, being inordinately stretched, perhaps even lacerated, the vessels themselves undergo serious injury, from which they may never recover. At this stage there is often absolute eversion of the lower part of the bowel; the mucous membrane is exposed, swollen and livid from intense congestion; and sphincteric power is more or less impaired.

Pregnancy and labour form the frequent starting-point of hæmorrhoids in women. The same act of distension, whilst the parts are turgid with blood, sometimes causes small lacerations of the edge of the anus, which, not healing, become fissures or ulcers. In some cases, again, the sphincter is found to have lost something of its contractile power. This loss is complete, or nearly so, when the sphincter has been torn through, as in many cases of laceration of the perineum. In these cases, the want of power to retain the fæces—incontinence,—observed after labour, is usually enough to suggest the true nature of the case, and, examination being made, the injury is revealed. In whatever way these lesions may have arisen, they are apt to be kept up by uterine disease, the two conditions exerting a mutually vicious influence. On the other hand, hæmorrhoids, fissures, and ulcers of the rectum and anus may be primary, or at least exist independently of uterine disease or displacement. The symptoms they give rise to may be taken by the patient, and in the first instance by the medical attendant, as evidence of uterine disease. And disease of the rectum, if involving much congestion and pain and difficulty in the performance of its function, by the consequent accumulations and straining, may induce congestion and prolapse of the uterus. Here, as in the converse case, the morbid condition of each organ exerts a vicious influence upon the other.

The displacements of the uterus almost always induce some rectal complication. In prolapsus simple, or with the usual attendant retroversion, the uterus falls into the lower part of the sacral hollow, and therefore projects more or less into the anterior wall of the rectum. It induces some degree of obstruction, to overcome which increased bearing-down efforts are excited. This increases the evil. The progressive prolapsus causing inversion of the vagina, the retro-uterine peritoneal sac is dragged down, and then the anterior wall of the rectum is drawn into a pouch, constituting vaginal rectocele. It is a matter of observation that the reduction of the displacement is frequently followed by the return of healthy peristaltic action.

In anteversion, the vaginal portion of the uterus is tilted up and back, so as to form a conical projection into the rectal cavity, easily felt by rectal digital touch. If, as often happens, the vaginal portion is congested or inflamed, exquisite pain is experienced when a stool is being passed. In some cases this pain on defecation is felt only, or at least is felt with especial severity, at the menstrual epochs.

In retroversion and retroflexion, the body of the uterus, most probably enlarged and painful, presses into the anterior wall of the rectum, encroaching upon its calibre, acting as a ball-valve, causing a degree of obstruction, paralysis, dyschezia, and retrograde or ascending disorder of the intestinal canal. Sometimes, in retroversion of the gravid womb, the strain upon the rectum is so great that actual tenesmus is induced.

The diagnosis of rectal from uterine or vaginal disease can be made by direct examination. Symptoms such as pain on defecation, pain when the sphincter acts, discharges of mucus or blood from the anus, will of course point to the seat of disease. But direct inspection is necessary to determine not only what is the exact morbid condition, but also what is to be done. I have insisted upon the importance of rectal exploration as a means of making a correct diagnosis of uterine disease. Thus in the course of examining for uterine disease we often discover rectal complications. But apart from this incidental exploration, when symptoms referred to the anus are complained of, special examination of this part should be made. I have several times in this way detected a fistula which had not been suspected by the patient. The rectum and anus may be examined, first, by the touch. The finger, oiled, is passed into the rectum and made to explore the cavity as far as it will fairly reach. In this way a polypus may be felt, or any tumour or constriction in the cavity; and we may judge how far the intrusion of the displaced uterus may be a cause of distress. Secondly, we may bring the lower edge of the rectum inside the sphincter into view by the following manœuvre: pass the forefinger (having well pared down its nail) into the vagina above the perineum, so as to get its tip as fairly over the seat of the anus as possible; then by depressing this strongly, the lower part of the rectum is everted and made to protrude through the anus. In this way hæmorrhoids, fissures, or ulcers, and the state of the mucous membrane, can be seen. Or, thirdly, the anal speculum may be used. By this aid we obtain inspection of the mucous membrane higher up, and can see a polypus or other morbid condition that may exist.

It is almost superfluous to say that constant irritation of the bowel, and especially the loss of power to retain the motions, is motive enough for suspecting the existence of laceration of the sphincter and perineum. It may indicate general paralysis. In this case, however, other signs of nervous disease will probably be detected. But incontinence of urine and fæces may be the earliest manifestation. Thus

I have had patients brought to me principally on this account, the grave disease of the nervous centres being not yet suspected by the patient or her friends.

Diarrhœa is frequent at the menstrual epochs, due no doubt to the increased irritation of the mucous membrane and the hyperæmia induced.

If we follow a similar order to that observed in the case of the bladder, we shall first study the *significance of retention of fæces.* This will lead us to the investigation of the causes of *obstruction.* Now, the need of defecation is far less imperious than that of micturition. If the bladder is not relieved within twenty-four hours such urgent distress ensues as to compel attention. But accumulation may go on in the bowel for many days. There is a further difference. If we except the case of strangulated hernia, it is comparatively rare for complete obstruction of the bowel to come on suddenly, as does obstruction of the urethra. These two conditions render the approach and existence of bowel-obstruction more insidious and more difficult to realise. In the majority of cases bowel-obstruction from pelvic disease comes on very gradually. As the obstruction increases, defecation is more and more difficult and scanty. Retrograde dilatation of the intestine above the obstruction takes place, which, by giving more room for the lodgment of fæces, affords some compensation for the want of outlet; the absorption of the watery constituent of the fæces, and the more scanty food taken, further tend to postpone the climax and to prolong the delusion that we have to deal simply with obstinate constipation. The climax is at length determined by the distension of the belly—partly by flatus, partly by fæces; by the abdominal pain; by the sense of distress that never fails to attend the non-fulfilment of a necessary function; perhaps vomiting; surely loss of appetite; earthy, dirty, yellow tinge of skin, due to empoisonment from absorption of fæcal elements and bile—a condition analogous to urinæmia, and for which I have proposed the name "copræmia"; and by the failure of purgatives and enemata to bring away fæcal matter. When things have come to this pass, a strict examination is imperative. If exploration of the abdomen discover no sufficient cause, we must explore the pelvis. This is done by the vagina and rectum. The instruments needed are the finger, the sound or a whalebone probang, the aspirator-trocar, and the enema-syringe.

Retention may be incomplete or complete. The retention caused by retroversion of the gravid womb is rarely complete; and the distress arising being of quite minor importance to the attendant retention of urine, the subject need not detain us. But there are cases of incomplete fæcal retention caused by retroflexion of the enlarged uterus in which there may be no serious retention of urine. In these cases the enlarged body of the uterus, rolled back into the sacral hollow, compresses the anterior wall of the rectum against the posterior wall, acting like a ball-valve. To some degree this difficulty and its retrograde consequences attend most cases of retroversion or retroflexion of the uterus. It is sometimes more pronounced when there is impaction of the uterus enlarged by fibroid tumours. Examination by vagina and rectum will reveal the true nature of the obstruction; the uterine sound will lift the mass out of its false position, and then a suitable pessary will keep it from falling back. Thus complete relief to the bowel is often attained. Obstruction from pelvic cellulitis or peritonitis is diagnosed by the signs described in the second lecture.* But something more is required. The patient under chloroform, the finger is passed as high as possible into the rectum, and, following its course, we come to the constriction caused by the fibrinous deposit nearly encircling the bowel, and nearly closing it by concentric contraction. I saw a case in which things had gone to such extremes that death seemed imminent. The stricture barely admitted a bougie. The pelvic brim was occupied by a dense mass matting all the organs together. It was difficult to decide whether this was due to malignant disease or to simple inflammatory effusion. I suggested as the only apparent prospect of relief the resort to colotomy. Whilst this was being debated, suddenly an immense gush of pus took place, the bowel was liberated, and recovery ensued. Such a lesson could not be forgotten. In several cases which have since come under my care I have penetrated the mass by the aspirator-trocar, and have thus drawn off pus with manifest relief. The marks of irritative fever will aid in raising the suspicion of imprisoned pus. But this kind of evidence is not wanted to justify the puncture. The operation, as far as I may judge from a considerable number of observations, is quite harmless, and its value in diagnosis and treatment is so great that I think it should be resorted to in every instance where local or systemic distress is manifest. I have even seen reason to believe that punctures thus made for diagnostic purposes have had a curative action by stimulating absorption of the effused material.

It is necessary to be provided with special trocars. The ordinary ones supplied are not available for intra-pelvic use. Messrs. Weiss have made for me trocars eight or nine inches long, supported on a firm stem, which answer well. They can be adapted, like the ordinary needles, to the same mount of the aspirator-tube.

Another disease which may proceed in a similar manner, and lead up to the same result, is cancer. Whenever this dire disease invades the mucous outlets or canals, it tends to close them by gradual concentric contraction. We see this in the œsophagus, in the anus, the vagina, and the urethra. So when it extends from the uterus, invading the neighbouring structures, it not seldom seizes the rectum about the sigmoid flexure, surrounds it, and, gradually closing in, the tube is reduced to the smallest bore, so small as to be quite inadequate to the function of defecation. In this way cancer occasionally proves fatal. All the signs of copræmia and starvation precede. In such a case the only hope of reprieve lies in colotomy. We may puncture by the aspirator-trocar; but nothing beyond diagnostic satisfaction will be gained.

Ovarian tumours have caused death by obstructing the bowel. Dr. Parker* relates a case. Rokitansky describes fatal constriction caused by the rotation of an ovarian tumour. When symptoms of dangerous bowel-obstruction supervene in connexion with ovarian tumour the expediency of immediately proceeding to extirpation must be earnestly discussed.

I have recently seen with Dr. Risdon Bennett and Mr. Berry a case of suspended action of the bowels, instructive as illustrating a considerable class of cases. A muscular tube depends for its healthy work on the freedom of its muscular action. This action is liable to be arrested or paralysed if the tube be encroached upon by inflammatory or other deposit in such a manner as to interfere with its mobility, or to lessen its calibre. Nay, the mere proximity to an inflamed or enlarged organ seems often to be enough. Whenever a function can only be exercised at the cost of pain, the system instinctively tries to avoid pain by suppressing the function. And there may be other causes of nervous diversion leading to this induced local paralysis.

In the case to which I am now referring, a lady, aged fifty-two, had ceased menstruating for two years, when suddenly metrorrhagia set in, and on one occasion amounted to flooding. At the end of two months constipation supervened, resisting for fourteen days the frequent use of enemata and opium. There was vomiting, but never of stercoraceous quality. We detected a tumour, in all probability of recent formation, in the right broad ligament fixing the uterus. It was presumed to be a blood-tumour or hæmatocele resulting from the rupture of vessels of the ovary or in the broad ligament. Examining by rectum, I could not find that there was any marked closure of the bowel. The arrest of action of the bowel admits of explanation on the theory just enunciated. It is analogous to the paralysis of the intestines attended by tympanites, and to the bladder-paralysis of puerperal peritonitis.

As in the case of the bladder, so in that of the bowel, we have to consider the significance of abnormal matters in the excretion. In both cases these may or may not be indications of disease of the organ from which they flow. Thus, blood, mucus, pus, may be the manifestations of dysentery and ulceration of the intestine or of hæmorrhoids. But they may spring from quite different causes. For instance, blood in considerable quantity is sometimes discharged in pregnancy, and in some forms of disordered menstruation. Whenever blood comes from the bowel apart from the obvious conditions of fever, dysentery, or liver disease, the possibility of pregnancy should be considered, and the pelvic portion of the bowel, with its relations, should be carefully examined.

---

* THE LANCET, Feb. 6th, 1875.

* Edin. Med. Journ., 1863.

Blood may come from a pelvic hæmatocele. It may issue from a dermoid or cystoid tumour. So may pus, hair, or bones, or teeth. Indeed, the rectum is the often elected channel for the voidance of the contents of most of the pelvic tumours. Abscesses resulting from pelvic inflammations most frequently empty themselves by this road; and this is also the favourite channel for the elimination of the fœtal elements of extra-uterine gestation cysts. Intrapelvic examination is essential for the recognition or the exclusion of these conditions. And this examination must be thorough. In urgent cases it may even be necessary to pass the whole hand into the rectum—of course whilst the patient is in a state of anæsthesia.

One lesson will be drawn from the clinical deductions made in these studies of the relations of bladder and bowel distress to disease of the neighbouring structures. You will see how impossible it is to pretermit close examination of the surrounding organs without serious risk of overlooking conditions that may be fatal if neglected, and which may be remedied if discovered. Whilst we are looking at the kidneys or the intestine, because they are disturbed in their functions, it may be the uterus or the ovaries that are in fault. We thus see how dangerous it is to practise in the spirit of pure specialism; how absurd it is to map out the body, and assign particular territories to particular classes of practitioners. You will see how intimately, how indissolubly that part of medicine which takes for its basis the particular study of the generative system in woman, is linked with the disorders of the alimentary, vascular, and nervous systems: that is, a pure specialty cannot exist. A more monstrous thing cannot be conceived.

Hunterian Lectures

ON

SYPHILIS,

AND ON

SOME LOCAL DISEASES AFFECTING PRINCIPALLY THE ORGANS OF GENERATION.

Delivered at the Royal College of Surgeons of England,

BY HENRY LEE, F.R.C.S.,
PROFESSOR OF SURGERY AND PATHOLOGY TO THE COLLEGE.

INTRODUCTION: INOCULATION OF SYPHILITIC BLOOD.

IN the previous lecture we considered Hunter's idea of the life of the blood, the way in which that ministered to the growth of every part; and, as illustrated by one disease, the way in which the nutrition of every part might be interfered with when that life was touched. In the present lecture we will consider the morbid processes by means of which it is so influenced.

The results produced in the human body by the syphilitic poison are so various, affect a patient's constitution at such different periods, and are apparently so dissimilar in different cases, that it is necessary in studying this disease to distinguish accurately if possible between the essential actions which belong to the disease itself, and the various complications which may arise from lapse of time, from weakness of constitution, from the differences in the manifestations in its earlier and later stages, and especially from effects of accidental complications, or from the modifications produced by its recurrence.

Hunter prefaces his treatise on the venereal disease by the description of four morbid processes or actions, to which he constantly refers in his subsequent remarks. Since his day the nomenclature of these actions has been much varied and altered; but, as conveying any distinct and definite ideas, I do not think that it has been improved. These actions he calls the adhesive inflammation, the suppurative inflammation, ulceration, and mortification.

But in order to make his description of these processes available for our present purpose we must also consider how these actions are modified by the structures in which they occur.

An animal body, Hunter observes, is composed of a variety of substances, and we have an opportunity of observing the comparative progress of disease in them, and their comparative powers of restoration, and we find that they differ very much from each other in those respects. The healthy and morbid processes in growth, decay, and repair are, however, regulated by the same living principles, or, if we please, guided by the same hand, in all living beings and in all diseases. In diseases arising from accident, a great difference in the degree of action takes place, according to the nature of the parts implicated: thus bone, tendon, ligament, and cellular membrane go through their morbid actions more slowly than muscle or skin. This principle is also abundantly illustrated in the different morbid processes produced by venereal diseases.

The same kind of action which produces an effusion of lymph upon the iris may, if it attacks the skin, be followed by a variety of modifications in the growth and development of the cutis or its coverings. If the cellular membrane be affected, an indolent tumour may result, which goes comparatively slowly through its stages, and may terminate in mortification, or perish by a still slower process of molecular necrosis. In the bones the same disease produces an increased development of bone, ulceration, or necrosis. In the lymphatic glands an enlargement is produced, confined strictly to those glands themselves, and not involving—at least, in the first instance, in any degree—the surrounding structures.

In internal organs the same disease may produce deposits, such as are illustrated in this preparation of syphilitic disease of the lung, and in this of syphilitic deposit in the liver. These deposits may be more or less perfectly absorbed, or more or less perfectly transformed, in the processes of nutrition and growth into tissue, resembling that of the organ in which they occur.

CASE 12.—A gentleman has a secondary syphilitic eruption and symptoms of disease of the lung. For the latter disease he consulted a number of medical men, and was for a long time under treatment. The symptoms, however, persisted. As he wished to go abroad, I was requested by Dr. Tuke to see him for his secondary symptoms before he went, and he was accordingly placed under treatment, which he had not time fully to carry out, but the eruption almost entirely disappeared, and with it all his lung symptoms. These had not returned two years afterwards.

CASE 13.—A patient in the Lock Hospital, many years ago, was pronounced by the physicians of the hospital to have one lung in great part consolidated. I did not know at the time what the disease might be, but I thought I would, at all events, treat his secondary symptoms. These disappeared, and with them the lung affection, and he was seen some months afterwards in apparently perfect health, following his occupation as an omnibus conductor.

The most important modification of increased action, as far as our present subject is concerned, is that which is observed in mucous membranes as compared with other structures in the body.

Hunter showed that a mucous membrane under violent irritation would, like a serous membrane, produce lymph; but, generally speaking, inflammation of a mucous membrane terminates either in resolution, an increased secretion of mucus, or in suppuration. But although the secretion from the surface of a mucous membrane differs in general from that of a serous membrane, yet the membranes themselves may be affected in a similar way. Effusion of new material may take place in their structures, and in the cellular tissue in contact with them. They may both become infiltrated, thickened, and permanently altered. With regard to the serous membranes, we often see an example of this, as in the case of old omental herniæ; and with regard to the mucous membranes, most interesting examples are afforded, in illustration of our present subject, in the formation of mucous tubercles, and in the more or less permanent thickening of the mucous membrane of the urethra. These will hereafter occupy our attention particularly. I will only at present note that the mucous membrane of the urethra may be thickened by the syphilitic poison, as shown by cases similar to the following, which in practice are not very uncommon.

CASE 14.—A young gentleman contracted syphilis, followed by secondary symptoms. He had never had gonorrhœa. In the course of the manifestation of the secondary affection the stream of water gradually diminished. He had apparently an ordinary stricture, which was cured by the specific treatment, without the use of instruments. There was no urethral discharge in this case.

When the venereal poison, Hunter observes, is applied to the skin, its effects are generally manifested first in a pimple, which is commonly allowed to scab. The scab is generally pushed off or rubbed off, and one larger than the first forms. Hunter defines this process of scabbing as the first mode of healing a wound or sore in which inflammation may be greater than where union can be effected, but not nearly so great as where suppuration takes place. We shall, I think, understand Hunter's idea in this respect by considering what he says with regard to the constitutional forms of the disease. "When the poison has got into the blood it there irritates to action. There are produced from that irritation many *local* diseases, as blotches on the skin or thickening of the periosteum and bones." These forms of disease he calls compound or constitutional; yet he says they are not strictly so, for every complaint, in consequence of the malady, is truly local, and is produced by the simple application of the poison to the parts. Now if this be true, as I believe under given conditions I shall demonstrate it to be, the distinction between what we have been in the habit of calling primary and secondary syphilitic affections in a great measure disappears; and in truth, in uncomplicated cases and in a healthy constitution, where there is no accidental cause of irritation, the local and the constitutional manifestations very much resemble each other, and are in fact of the same nature. One of the first cases of syphilis which I recollect affords an illustration of this.

CASE 15.—A boy, scarcely arrived at puberty, had a small, circular, slightly elevated induration on the skin of the penis. This soon became covered by a thin scale. In due course a scaly eruption appeared on the body, and the appearances of these very accurately resembled the primary affection. The disease ran its course without ulceration or suppuration of any part.

CASE 16.—A gentleman had a small crack on the middle of the lower part of the prepuce, which had often caused him some annoyance. On one occasion, after a suspicious intercourse, the edges of the crack became indurated. The induration was to a very limited extent, perfectly circumscribed, and was accompanied by enlarged glands in the groin. He could hardly believe that it was of any consequence. It was, however, followed by a specific eruption, which continued, on and off, for about three years; but none of the secondary manifestations ulcerated or suppurated.

CASE 17.—A gentleman had a very slight induration on the skin on the right side of the penis. It was quite unattended by any irritation or ulceration, and so slight that I doubted at first as to its nature. It however persisted, was accompanied by slightly enlarged glands in the groin, and remained accurately circumscribed. I then told him my opinion. He, however, did not think it could be syphilitic, so trifling was it in appearance. In due time, however, a scaly eruption appeared on the body, and continued on and off slightly for several years. This patient had never had gonorrhœa, but as the successive secondary manifestations of syphilis developed themselves he had occasionally a thin discharge from the urethra, unaccompanied by any ardor urinæ. It had the appearance of thin gruel, and left a stain upon the linen. I have no doubt but that it arose from a secondary inflammation of the mucous membrane of the urethra. Now these, and many more which I could mention, afford illustrations of adhesive inflammation only. In both the primary and the secondary affections an attempt was made to heal by scabbing, but in this disease the attempt does not succeed, and successive scabs or scales are formed. These are all modifications of the adhesive inflammation, which would terminate in resolution if its cause were not persistent. Many drawings of my own and of others demonstrate the fact that what we call the primary disease may go through its stages without any suppuration and without ulceration; and here I would observe that it is a characteristic of both the primary and secondary affections of this disease that in uncomplicated cases they leave no scars on the body. They are attended with no loss of substance, and, as we shall hereafter see, the artificial inoculations from these affections follow the same rule. It is quite true that it comparatively seldom happens that the syphilitic poison runs its course without some accidental causes of irritation. This may depend upon some other irritating fluid being applied at the time of inoculation, upon want of power in the patient's system, or upon the changes which occur in the original products of the adhesive inflammation. The true characters of this inflammation in primary syphilis are given by Hunter with comprehensive clearness and brevity. The process results in a peculiar thickening, very circumscribed, not diffusing itself gradually and imperceptibly into the surrounding parts, but terminating rather abruptly. This description is perfectly true, whether the induration be scarcely thicker than a layer of cuticle, or whether it involve the whole thickness of the skin. It retains these characters through all its stages, though they may be obscured by accidental circumstances. The secondary affections also maintain this circumscribed character, but are unattended with the peculiar defined induration, for a reason which will hereafter be more fully considered. This induration, according to the Hunterian doctrine, depends upon the effusion of lymph, the product of adhesive inflammation. If the lymph were produced from a non-specific cause, it would be organised and converted into a tissue similar to that of the surrounding part, and ultimately anything that was redundant would be absorbed. But the life of this lymph is touched with the same disease as the blood, or the products of the blood from which it is derived. It has a vitiated existence, and tends soon to pass, except in very vigorous constitutions, into a state of degeneration. This may manifest itself in various ways: (1) by an unhealthy formation of epithelium, producing various kinds of scabs and scales; (2) by unhealthy growth of the hair, nails, or teeth; (3) or by the effusive matter itself undergoing a kind of molecular necrosis, suppuration, or ulceration. These latter processes, although they may occur in all stages of the disease, are most marked when the poison is first received, because then acting on a virgin constitution. Accordingly, we find that the adhesive inflammation first produced, in the majority of cases passes from the adhesive stage to some other form. The product is no longer fit for the life of the part, and is thrown off in one of the forms above mentioned. A double action then goes on, one of adhesive inflammation, accompanied by induration, another of the throwing off of diseased cuticle, or suppuration or death of the newly formed tissue.

These two consequences, the induration and the destruction of the newly-formed tissue, as Babington has observed, seem to be distinct and independent actions, since, although they generally exist in conjunction, they are sometimes found separate, one or the other of them being in some cases wanting. These two processes may sometimes be witnessed in the same case at different times under the influence of treatment. A patient may have a well-marked primary induration, and under the action of mercury the induration will disappear, and a soft sore will only for a time present itself, but after an interval the induration will reappear with its specific characters.

Now, all the cases which I have given in the previous and in the present lectures are instances in which the poison of syphilis produced at first the adhesive action only, by means of which the nutrition of parts was more or less perverted, both in the primary and secondary manifestations of the disease. Coinciding with and confirming these practical observations are the results of direct experiment.

CASE 18.—A patient, under the care of M. Puche, in the Hôpital du Midi, was inoculated on the abdomen on the 29th of January, 1861. The inoculated matter was taken from an indurated chancre, which had existed six weeks, and which was followed by secondary symptoms. On the 19th of February, as no result had appeared, the patient was inoculated from another indurated chancre. On the 8th of March, thirty-nine days after the first inoculation and seventeen after the second, two little pimples appeared on the inoculated spots. The first became excoriated after the lapse of some days, but the second presented on its summit a small point of suppuration. Both presented the specific induration of primary chancres. On the 10th of April this patient had a general eruption of roseola.

CASE 19.—Rinecker records the following:—On the 13th February, 1852, an inoculation was made on Dr. Warnery. This was effected by means of a blister. The blistered surface soon healed. On the 9th of March, however, it became inflamed. Infiltration had taken place in the skin, which was hard and thickened. On the 21st of March, thirty-five days after the inoculation, and thirteen after the appearance of the specific primary symptoms, the blistered surface was covered by a mass of tubercular excrescences. These were copper-coloured, raised above the surface, and in some places confluent. They were covered for the most part with brown crust, slightly adherent, or with thin grey scales. Eleven weeks after the inoculation he had severe pain in the head, followed by a syphilitic eruption on the head and face. This was succeeded by inflammation of the soft palate and neighbouring parts, with a superficial exudation of lymph. Ultimately mucous tubercles appeared on the scrotum, the perineum, and on the inside of the thighs.

CASE 20. (Related by Baerensprung.)—M. C—— had never had syphilis. She was inoculated on the right thigh from an indurated chancre in three places. The inoculation was made on the 28th of May, 1859. On the 1st of June the inoculated spots appeared as little red points, without any surrounding inflammation. On the 6th of June it was impossible to distinguish them. On the 25th, however, three little red tubercles appeared on the inoculated parts. On the 5th of July the corresponding glands in the groin were enlarged. The tubercles were also considerably increased in size, and ulcerated on their surface. On the 12th, two of the tubercles had united, and presented a raised, accurately defined induration. The inguinal glands were very hard, and not painful. On the 20th this ulceration was the size of a franc piece, with a base almost as hard as cartilage. There was no suppuration, but the surface was covered by an adhesive secretion. On the 29th there was an eruption of roseola and mucous tubercles.

CASE 21. (Recorded by Lindwurm.)—M—— had never, as far as could be ascertained, had syphilis. She was inoculated with the secretion of two indurated chancres of a patient who at the same time had secondary symptoms. No immediate results followed. Fifteen days after the inoculated points reappeared as two little red stains, which insensibly became transformed into little reddish-brown tubercles. On the 28th there was superficial erosion of these little tubercles, followed by excoriations covered by thin brown crusts. On July 8th these so-called ulcerations had increased and were surrounded by slight induration. The corresponding inguinal glands now became enlarged, and subsequently the glands in the opposite groin. A papular eruption followed, especially upon the organs of generation.

CASE 22. (Also recorded by Lindwurm.)—A young woman was inoculated with the secretions of the chancres of the previous case on the 10th of July, and again on the 12th. Some small pustules followed these inoculations, and became covered by small scabs. The whole of these inoculations were healed in seven days—namely, on the 17th of July. On the 29th of July, however, although all traces of the inoculations had previously disappeared, five red tubercles, corresponding with the inoculated points, showed themselves. These tubercles became covered by thin crusts, and converted into indurated chancres. In the middle of September the manifestations of constitutional syphilis were developed.

CASE 23. (Recorded by M. Rollet.)—A patient was inoculated from an indurated chancre. Eighteen days afterwards a papule was developed, which became ulcerated on its surface. This, as M. Rollet believes, was prevented from being developed into a regular indurated chancre by antisyphilitic treatment.

The examples of artificial inoculation hitherto given are cases in which the inoculated matter was taken from primary syphilitic sores. The following are instances in which the inoculated secretion was taken from some secondary affections.

CASE 24. (Reported by Gibert.)—A patient, affected with lupus of the face, was inoculated on the left arm, by means of a blister, with the secretion of mucous papules from the anus of another syphilitic patient. Five days afterwards there was no trace of the effects of the inoculation, and at the expiration of nine days a little redness only was left on the blistered surface. On the eighteenth day of the inoculation a raised copper-coloured papule appeared on the inoculated spot. On the twenty-second day a little exudation appeared on the surface of the papule, which was enlarged. On the twenty-ninth day there was an enlarged gland in the corresponding axilla. On the thirty-second day a crust was detached from the surface of the papule, which was superficially excoriated. On the fifty-fifth day the papule had become converted into a tubercle, which was superficially raised and indurated. Some red spots now appeared on the body. These soon showed themselves also on the anterior surface of the arms, the inside of the thighs, and the inguinal regions.

In another instance (Case 25) mentioned by Gibert, the period of incubation between the inoculation and the appearance of the first local symptoms was twenty-five days. A little redness then appeared, followed first by a dry papule, which subsequently became moist and excoriated. It then became covered by a crust and indurated, and ultimately became a tubercle, which ulcerated on its surface, as in the preceding case. A corresponding lymphatic gland became enlarged, and thirty-seven days after the inoculation a rash of roseola manifested itself on the patient's body.

CASE 26. (Reported by Lindwurm.)—A patient affected with lupus had a small blister applied to the neck. On the blistered surface a small piece of the mucous membrane of a syphilitic tubercle on the lip was applied. The wound in the neck appeared to heal in five days, but three weeks later the wound again inflamed, and an ulcerated papule appeared. This was followed by enlargement of the cervical glands and copper-coloured blotches.

CASE 27. (Reported by Wallace.)—A young man was inoculated in three places on each thigh from the syphilitic pustules of another patient. In this case the punctures were first made, and the secretions of the pustules applied to them. The punctured spots did not inflame. Thirty days afterwards the patient complained of heat on the inoculated spots. Two of the spots on the left thigh, and all three on the right, presented little raised pimples of a reddish-brown colour, with faint scales on their surface. One of these scales became a scab, and when raised exposed a superficial ulceration. The corresponding inguinal glands were enlarged. The pimples soon became converted into ulcerated tubercles, which were round, slightly depressed in the centre, and of a dirty white colour, like condylomata. A scaly eruption on the body followed.

CASE 28. (Reported by Vidal.) — M. Boudeville was inoculated on the 1st of November with the secretion of a pustule from a syphilitic patient. A papule appeared on the 3rd; this became covered by a crust, under which some pus formed. This continued until the 15th, when the local inflammation subsided. Thirty-five days afterwards, however, a fresh action commenced. Two fresh pustules made their appearance at the inoculated points, and were very long in healing. Flat lenticular pustules on the head, loss of hair, enlargement of the cervical glands, sore-throat, mucous tubercles, and an eruption of roseola followed.

CASE 29. (Reported by Rinicker.)—On the 9th of January, 1852, a young physician was inoculated on a small blistered surface with the secretion of a syphilitic eruption of a child. On the 10th no visible effects had followed the inoculation. On the 20th there was a papular eruption around the inoculated spot. This soon disappeared. On the 2nd of February a fresh action commenced. The surface which had been blistered was red, itching, and scaly. Twenty-nine days after the inoculation this surface was of a deep red-copper colour, the skin was hard and infiltrated, and presented several papular elevations. On the 10th of February the whole surface which had been blistered was covered with reddish brown, hard tubercles, covered with scales. In spite of the use of mercurial ointment, these local affections were followed by ulceration of the palate, of the lower lip, and of the left side of the frænum of the tongue, and later by mucous tubercles on the scrotum.

CASE 30. (Reported by Waller.)—A boy of twelve years of age was inoculated with the matter from a syphilitic patient on the 6th of August, 1850. The matter was placed by means of a small piece of wood and lint on wounds made by a scarificator. At the end of four days the wounds made by the scarificator had healed. On the 15th of August there were some red spots on the inoculated parts, and on the 30th fourteen tubercles presented themselves in the same situation. These were of a dirty red colour, hard to the touch, and almost exactly circular. Some of them presented a slight desquamation. The following days the tubercles increased in size, and all became confluent. When the crust was removed, the tubercles appeared slightly excoriated, raised, and flat. They soon again became covered by fresh thin scales, which were of a grey colour and dry. Twenty-seven days after the appearance of these tubercles, and fifty days after the inoculation, a syphilitic eruption appeared, which soon covered the whole body.

A SECOND SERIES OF

CASES ILLUSTRATING THE TREATMENT OF HÆMORRHOIDS AND PROLAPSUS BY THE CLAMP AND CAUTERY.

By HENRY SMITH, F.R.C.S.,
SURGEON TO KING'S COLLEGE HOSPITAL.

(*Concluded from p.* 90.)

Now I have spoken of pyæmia, I am happy to state, as before, that I have not met with a case after this series of operations; at least, fortunately, I have not been able to verify it as such. But in November last I was very anxious about the condition of a distinguished member of our profession, who, somewhat like Dr. Frank's patient, had long suffered from severe hæmorrhoids and chest symptoms, and had been advised not to submit to any operation. Wearied at last by his complaint, he submitted. The operation was a severe one, and was followed, as is most unusual, by much constitutional disturbance, great depression, quick pulse, anxious countenance, and unhealthy discharge from the wound. For some days I was anxious about him, and thought I was going to have, what I had never seen after this operation, a case of pyæmia. Very careful attention to his nourishment, however, the use of opiates, and washing out the bowel with warm water, gradually removed the symptoms, and I had the gratification of seeing my patient, who is an ornament to our profession, entirely recover, having been immensely benefited by the operation. I have before stated, and I think so now, that pyæmia after the use of the cautery is most unlikely to occur; it is odd, however, that I have not met with any cases, for it is often necessary to make extensive wounds in the integument, to which the cautery of course is not applied.

Erysipelas is the next complication of which I must speak. In the 300 cases I had not one instance; but, curiously enough, in the last 100 I have had two—at least one of the cases was decidedly a well-marked instance of the disease, spread over the whole of the buttocks and back, and nearly killed my patient. I may mention, however, that he had been terribly reduced by his disease, consisting of a huge prolapsus, and that I had to make extensive incisions for removing external tumours. Erysipelas was, moreover, very rife in my practice at this period. At this very time, and in the same neighbourhood, another gentleman got rigors, fever, and a large abscess in the buttock, from which he recovered, although he was seventy-eight years old. I believe I took the erysipelas from my other patient to this. It has been a matter of surprise and congratulation to myself that I have not much more frequently met with erysipelas after this operation. I believe that the immunity is due in great measure to the action of the cautery—an explanation similar to what holds good in instances of burns; however extensive these are, it is a comparatively rare thing to find erysipelas attack such a wound.

I come now to the consideration of hæmorrhage—the most important matter in connexion with the operation of the clamp and cautery. Important in two senses: first, because it is in reality the only objection to the operation; and, second, it is the result against which the surgeon has most to guard, and unless he takes very great care it is an occurrence very likely to take place. I find, moreover, from what has been written, and from conversation with my professional brethren, that surgeons dread the performance of the operation from fear of this taking place. But I have no hesitation in saying that the bleeding which is most likely to be serious—viz., that which may take place immediately after the operation—ought not to occur, and that if it does happen it is either from the fault of the operator or from the use of defective instruments or an inefficient use of the cautery. As to my own results, I may state that in the whole of my 400 cases, which have included many of the severest kind and of huge size, I have never met with bleeding sufficient to necessitate plugging of the rectum; and not one of the house-surgeons of King's College Hospital have ever had to resort to that measure. In fact, I have been astonished that a case has never occurred to me where this measure has been needful, as, especially in hospital cases, I have frequently been very sparing with the cautery, and have become emboldened by success from paying as much attention as I ought to prevent its occurrence. I have met with eight cases in which bleeding, either immediately on the operation or that which may be termed secondary hæmorrhage, has taken place to such an extent as to demand very active measures short of plugging the rectum; and, curiously enough, at least six of these have occurred in my last series. I account for this—and glad I am, in one respect, to be able to say this—from my previous immunity causing me to take less precautions than I should. This little salutary experience, which I will relate, has made me doubly careful, and I do not think that my future results will show any similar mishaps.

The first case occurred in the person of a young woman in most miserable health, who had suffered terribly from hæmorrhage, and came into the hospital with severe hæmorrhoids. I performed the operation with the clamp and cautery. A few days after she got pain in the pelvic region, with constitutional disturbance, and the action of the bowels was followed by smart bleeding, and it recurred on two occasions. It was arrested on each occasion by the injection of iced water, and she got quite well. I cannot take any blame to myself in this instance. Either some vessel must have escaped the action of the cautery, or the blood was in such an impoverished state that there could not have been coagulating power enough to close thoroughly the vessels. I have operated on many such cases, however, and have not had any bleeding; in fact, it is in such cases as this that I believe we find the special advantages of the cautery. I once saw, in a similar case, where ligature was employed, nearly fatal secondary hæmorrhage ensue after the separation of the threads.

The second case occurred in a hospital patient, a man. Smart bleeding occurred after the action of the bowels, which, however, was stopped by the injection of iced water. In hospital cases I am not so particular in applying the cautery, as I know there is assistance handy if bleeding should occur. I think it very probable I did not cauterise sufficiently here. Both these cases were examples of secondary hæmorrhage proper, which is very rare indeed.

Sometimes a good deal of blood is passed on the first action of the bowels. The patient gets alarmed, and I am sent for; but on examination it is found that the greater part of this evacuation consists of dark coagulated blood, which had evidently slowly escaped into the bowel after the operation, and had remained there until the action took place. The third and fourth cases were of this description. In the one the bleeding ceased spontaneously; but in the other some arterial blood was poured out, and my assistant, who was called to the case in my absence, was obliged to pass a large speculum into the bowel, screw it up, and allow it to remain until I arrived. This answered most effectually. Now in both these cases I take blame to myself. In each there was a mass of internal hæmorrhoids, which I clamped and cauterised in the ordinary manner; but, in addition, there was a large mass of external growths, covered partly by mucous membrane. I removed them with the scissors, but did not apply the cautery to the bleeding surface, as I have done since in instances where the muco-cutaneous growths, as I would term them, are very large. When the cut parts are returned after the operation, of course the wounds which were external become converted, as it were, into internal, and vessels which have been divided and have not been cauterised are very liable to bleed. Many years ago I saw a nearly fatal case of hæmorrhage from this cause.

The fifth case was an instance of bleeding coming on immediately after the operation, and, excepting the last case I shall mention—which, however, is not exactly similar,—it is the only instance of the kind I have met with, although I have been constantly expecting it, and have wondered at its non-occurrence. I operated on a gentleman for large internal hæmorrhoids. In clamping the largest tumour, and after dividing it and cauterising, a portion of the cut pedicle slipped away, and on unscrewing the instrument I noticed a vessel bleeding freely; it retracted, however, and apparently ceased to bleed. I finished the operation, and returned the parts. In about ten minutes, just as my assistants and myself were about to take our departure, the patient suddenly called out that his bowels were about to act; and immediately a large gush of blood took place, making him very faint. I at once introduced a large silvered glass speculum into the rectum, when another large gush of blood took place, and the bleeding continued for some moments, but by pressing the speculum well in I stopped it very quickly. The speculum was retained for about a quarter of an hour, and the bleeding did not recur. This might have been a serious case if I had left the house; and doubtless I was very blamable, in the first place, for allowing a portion of the pedicle to slip, and, in the next place, for not applying the clamp again and cauterising the vessel, which of course had not been touched at all by the hot iron.

The sixth and last case was one of a peculiar character. It occurred last July, in the person of a gentleman who suffered severely from internal hæmorrhoids; one was a large solid growth, more like a polypus, and having a thick solid pedicle. Before putting on the clamp I made a free incision around its circumference, and in doing so I wounded a large vessel; it spouted forth its contents over me, and then retracted, and, as I supposed, ceased to bleed. I embraced the tumour with a large clamp, inserting the blades into the cut surface, and removed the growth, freely cauterising the pedicle. In about an hour the patient felt very faint, and was obliged to resort to measures to relieve this; shortly afterwards, however, this condition passed away, and he felt pretty well until about forty-eight hours after the operation, when he had a strong desire to evacuate the bowels, and he passed a large quantity of coagulated blood. He made a very quick recovery. Now in this case there was a very narrow chance of the patient having a serious hæmorrhage, and I was much to blame; for there can be no doubt that the large vessel which I had divided, and which had apparently ceased bleeding, burst out afresh on the completion of the operation, but was arrested by two causes—namely, the fainting, and the coagulation of the blood acting as a plug. I ought not to have trusted to the powers of nature to arrest bleeding from so large a vessel, but should have drawn the part down and have clamped and cauterised that as well as the rest of the pedicle.

It is a somewhat curious circumstance that in the majority of the cases where bleeding occurred it happened in the last series of operations, and I have no doubt is entirely explained by the fact that repeated operations at an earlier period of my practice without any hæmorrhage occurring had made me bold and somewhat careless; for when I first began to perform this operation I had a constant dread of hæmorrhage, and used to apply the cautery so freely that bleeding could not take place. I have, however, since the occurrence of the cases I have detailed, returned to my former method of free cauterisation, and I do not believe I shall get any further cases of bleeding.

One other point in reference to the result of this operation, about which I have often been questioned, is as to the liability to the occurrence of stricture. My experience shows that stricture is not likely to occur from clamping and cauterising mucous membrane, but it is just as likely to occur after this operation as after any other operation when the skin is too freely dealt with. I have had three cases where, from this cause, cicatrisation of the skin caused a contraction of the anus; and hence I am extremely careful about the removal of skin, and only adopt this measure where there is an abundance of this tissue, or where, in consequence of great weakening of the sphincter, it is necessary to produce firm cicatrisation. If, however, I am obliged to remove skin at all freely, I always make a patient use a bougie for a few weeks.

In one instance only have I met with a case where a fistula resulted. In this case I had not the charge of the after-treatment, and therefore do not hold myself responsible for the result.

ANALYSIS OF TWELVE CASES OF PNEUMONIA,

ADMITTED INTO WESTMINSTER HOSPITAL DURING THE MONTHS OF MARCH, APRIL, AND MAY OF THE PRESENT YEAR.

By F. DE HAVILLAND HALL, M.D. Lond., M.R.C.P.,
MEDICAL REGISTRAR TO THE WESTMINSTER HOSPITAL.

(*Concluded from p.* 91.)

No. 6 was a very ordinary case of pneumonia of the right base, and does not present any feature of particular interest.

No. 7, on the contrary, is an example of one of the difficulties in the diagnosis of pneumonia. As the notes are very brief, I will give them as they occur in the ward-book.

E. D——, female, aged twenty, admitted April 19th. Illness began on April 12th with earache (no discharge), followed by cough, rigors, and pain in the right side. She took to her bed on the 15th. At present she complains of pain across the chest. Pulse 144; respiration 44, jerking. Right side dull up to nipple in front and midway between spine and angle of scapula behind. In front there is a little crepitation, with distant and feeble bronchial breathing; behind, only very feeble breathing; vocal fremitus and resonance so feeble as to be almost imperceptible. Sputa viscid, and inclined to be rusty. Heart: nothing abnormal, not displaced. Left chest healthy.

The physical signs continued much the same till her death on April 22nd, the only alteration being that there was no air to be heard entering the lower two-thirds of the right lung, and there was entire absence of vocal resonance and vocal fremitus over the dull region.

The autopsy, which was made thirty-two hours after death, revealed the following condition of affairs:—The lower and middle lobes of the right lung were in a state of red hepatisation, passing into grey; the main bronchus was occupied by a fibrinous deposit, which extended throughout the bronchi down to those of the fourth and fifth magnitude. There were also evidences of recent pleurisy and pericarditis.

Dr. Fincham, under whose care the patient was, had suggested that the cause of this anomaly was obstruction to the main bronchus by a plug of mucus; which is the view Skoda takes of these cases, the physical signs of pneumonia being sometimes restored after a violent fit of coughing. No amount of coughing, however, would have displaced the exudation in this case, as it was of a very firm consistence. Extensive closure of the bronchial tubes is, according to Walshe, the usual explanation of this occurrence, though it may also be due to pressure on the bronchus by an enlarged gland or tumour.

No. 8.—D. B——, aged twenty-nine, a labourer, admitted April 26th. He says that he slept out of doors all the night of the 21st, and was taken ill next day with rigors and pains in the limbs; cough began the same night. On admission: Face slightly livid; faint yellow tinge of conjunctivæ; pulse 128, feeble; heart-sounds normal; respiration 32; temperature 102°; left lung quite healthy; right lung dull down to second rib; feeble breathing; slight crepitation at end of inspiration; increased vocal resonance; heart-sounds heard unduly loud; the next two spaces resonant, very little air entering, and below hyper-resonance, with fair vesicular breathing; posteriorly the lung is dull up to spine of scapula, with fine crepitation, tubular breathing, bronchophony, and increased vocal fremitus; abundant frothy, watery sputa, with some viscid rusty sputa. Urine: specific gravity 1016; acid; faint trace of albumen; chlorides diminished.

On the morning of the 28th his temperature was 103°, pulse 140, and respiration 36. Furiously delirious during the night; out of bed several times. Quite delirious now, constantly trying to get out of bed. Too exhausted to be examined much. Got out of bed about 6 P.M., and died five minutes afterwards.

The post-mortem examination showed that the upper and lower lobes of the right lung were solidified throughout, in the condition of grey hepatisation; and that the upper lobe was in the more advanced condition, beginning to break down. Middle lobe quite healthy. In the left lower lobe, a piece of lung of the size of a small orange was in a state of grey hepatisation, the lung-tissue surrounding it being fairly healthy, except that it was œdematous.

The most interesting feature in this case was the implication of the upper and lower lobes in the pneumonic process, the middle lobe being unaffected. I have not met with a similar case. During the life of the patient the opinion formed from the physical signs was that he had phthisical consolidation of the apex and pneumonia of the base. One other point is also worthy of remark, and that is the extreme restlessness of the patient just before death. I have seen two or three cases of pneumonia lately in which the patients have insisted on getting out of bed to use the night commode or for some other purpose, death ensuing almost immediately afterwards.

No. 9 is a case of pneumonia complicated with pleurisy and pericarditis. The patient had previously been in the hospital suffering from pericarditis, though what it was due to did not clearly appear. He left the hospital on May 17th, by his own wish, and was readmitted on May 20th.

R. T——, aged twenty-seven, an ostler. He states that he was taken ill on May 19th, with rigors and sharp pain in the left side, as if "knives were being jobbed in." Spat up two ounces of black blood yesterday. Has had a cough the last three days. Temperature 104·6°; pulse 116, full, soft; respiration 36, shallow, painful. Lying on right side, too exhausted to be examined.

May 21st.—Right side normal. Left apex, good resonance and vesicular breathing; dull up to fifth rib; faint tubular breathing; the dulness gradually increasing towards the back, reaching to midway between angle and spine of scapula. Posteriorly there is loud tubular breathing and bronchophony; absent vocal fremitus; pleural friction in infra-axillary region. Sputa viscid, rusty; respiration 48; pulse 108, full; chlorides almost absent from urine; temperature, morning and evening, 103°. He was ordered carbonate of ammonia, brandy, and a jacket poultice.

22nd.—Pulse 112, of fair volume; respiration 52, panting; countenance somewhat dusky; sputa viscid, rusty. Had a very bad night. Posteriorly the left side is dull all the way up, with loud tubular breathing. Vesicular breathing at left apex anteriorly. Right side normal. He seems much distressed and is very restless. Urine slightly albuminous and containing hardly any chlorides. Temperature: morning, 102°; evening, 102·4°.

23rd.—Not much change, except that his temperature fell in the morning to 99·8°; evening, 101°.

24th.—Pulse 148, very feeble and running; respiration 52. Dull up to third interspace anteriorly, but not transgressing the median line; vesicular breathing above; loud pericardial friction sound. Posteriorly the chest is dull up to the spine of the scapula, with tubular breathing, but no vocal resonance or fremitus. Aspect very distressed, livid; conjunctivæ jaundiced. Urine bile-stained, containing one-sixth of albumen. Morning temperature 100·4°.

25th.—Died at 2 A.M.

The post-mortem examination showed the whole of the lower lobe of the left lung, except a small patch at the base, to be in a state of grey hepatisation; the upper lobe was œdematous. The lung was closely adherent to the costal pleura by a thick layer of lymph, resembling half-melted butter in consistence. About half a pint of straw-coloured serum in pleural cavity. Right lung healthy. Pericardium much dilated, containing half a pint of light-yellow serum. Surface of pericardium like a nutmeg-grater, with some shaggy lymph hanging from it, but no adhesion. Liver and kidneys in a state of cloudy swelling.

No. 10 is only noticeable for the extremely rapid way in which the physical signs of pneumonia cleared up.

J. B——, aged twenty-one, a stonemason, admitted on the 1st of May. Taken ill on April 27th with rigors, heat of body, pain in the right side, and cough. On the day of admission he was too exhausted to be examined; his temperature was 103° F., and at night it went up to 105°, the next morning it had fallen to 100°, and, although the sputa were still rusty, there were no physical signs of pneumonia; by the evening his temperature was normal. Discharged on the 14th of May, quite well.

No. 11.—T. W——, aged thirty, a labourer, admitted on the 14th of May. In this patient the pneumonia commenced at the left apex posteriorly, the day after his admission tubular breathing being heard over the scapula, but there was no increased vocal resonance or fremitus in spite of the dulness. On the next evening (16th) fine crepitation was heard all over the upper lobe posteriorly, and loud tubular breathing; and on the morning of the 17th the pneumonic process had extended to the front, as there was dulness at the left apex down to the second rib, with fine crepitation. On the 20th he had slight epistaxis; his temperature was 101·6°, on the 21st it had fallen to 99°, and on the 22nd it was 98°, so that the epistaxis may be considered in the light of a critical phenomenon. The delirium of this patient was of a very violent character, as, according to my experience, is so frequently the case in apex pneumonia. Huss remarks, however, that this is not especially the case. Besides being delirious, he was at times very restless at night; for which he had chloral prescribed, on one occasion with the effect of giving him an hour's quiet sleep. In several other cases of pneumonia I have seen it given with a satisfactory result. Dr. Habershon, however, says it is not a safe drug to employ where the respiration is liable to embarrassment.

No. 12—the last case—occurred in a healthy youth of the age of eighteen, a porter. He states that he was quite well up till the morning of May 14th, when he was taken suddenly ill about 10.30 A.M. with frontal headache, followed by pain in the chest; has not had rigors. Cough commenced on the 16th. Sputa were blood-stained on the 17th. Temperature on the evening of the 18th, the day of his admission, was 103·2°; the next morning it went up to 104·2°. Physical examination showed that the middle of the right lung was affected, as from the angle to the spine of the scapula there was dulness on percussion, with tubular breathing and loud bronchophony; at the angle of the scapula there was a little fine crepitation; both above and below the dull region there was good resonance, with fair vesicular breathing. The sputa were rusty. Pulse 108, feeble, dicrotous; respiration 44 per minute. On the evening of the 19th the temperature had fallen slightly, being 103·6°, and it continued falling, so that by the evening of the 21st it had reached 98·4°. The physical signs on this day were a little medium crepitation at the apex of the right lung in front, posteriorly quite resonant up to the angle of the scapula, from there to the spine of the scapula impaired; above the spine, resonant. Vesicular murmur, with medium-sized crepitation, over the dull region, with increased vocal resonance. Pulse 96; respiration 44.

May 22nd.—Pulse 72, very small and feeble; respiration 32. Only very slight impairment of resonance over the right scapular region, where the breathing is feeble, with occasional crepitation.

For the next five days the temperature kept below normal. He was discharged on the 4th June, perfectly well.

The chief points to be noted in this case are the limitation of the pneumonic process to the middle and posterior part of the right lung, the anterior surface being unaffected, and the rapid fall of temperature on the fifth day of the disease, which continued to drop without any break till the morning of the 23rd, when a temperature of 97·4° was recorded. This patient also afforded an instance of loss of sensibility about the bladder, as he allowed it to become much distended without making any complaint, but was able to pass his water when urged to do so.

Since May 18th, the date of admission of the last of these cases, four patients suffering from pneumonia have been admitted into the Westminster Hospital, and have all done well.

STRANGULATED UMBILICAL HERNIA.

By W. C. ARNISON, M.D.,

SURGEON TO THE NEWCASTLE INFIRMARY.

On March 20th I was requested by Mr. Charles Carr, of this town, to visit Mrs. D——, aged thirty-eight, mother of eight children, suffering from strangulated umbilical hernia. The history was a very common one. The hernia appeared seven years ago, after one of her confinements. No truss was worn, and not much inconvenience felt. On reaching the house, we found that an enema, which Mr. Carr had ordered in the morning, had been followed by a very large evacuation, with great relief to all the symptoms. It was therefore decided to defer any operation, as the hernia had always been, as it then was, irreducible.

On March 23rd Mr. Carr again requested me to see the patient, as the symptoms had returned after a period of relief, and there was now stercoraceous vomiting, its first appearance, although symptoms of strangulation had existed, more or less, for twelve days.

The patient was of the corpulent build so common in these cases. At the umbilicus was a lobulated tumour, the smaller portion as large as a walnut, prominent, and thinly covered with skin; the larger portion, buried in a thick layer of subcutaneous fat, could be felt under the integument. Attempts at reduction had failed, and the time for delay had clearly passed; an immediate operation was therefore advised and submitted to.

With the patient under chloroform, a last attempt was made to reduce the hernia. That failing, an incision was made in the median line on the lower side of the tumour, and the sac readily reached. Finding it impossible to get even the finger-nail between the sac and the edge of the umbilical orifice, I was compelled to lay the sac open, and then readily returned a considerable knuckle of intestine. The opening was still occupied by omentum, which could not be returned until I had traced it up into the smaller portion of the original hernia, into which it passed through an orifice so narrow as to require enlarging by the knife, after which it was easily hooked out by the finger and passed into the belly, leaving the ring clear. The wound was then closed by sutures, covered with a compress, and the whole secured by a broad calico band pinned tightly round the body.

The operation was concluded at 6 P.M. About three hours afterwards the bowels acted of their own accord, and during the following day flatus was freely passed. On March 25th there was vomiting, which soon ceased; and on the 26th the bowels again acted freely. The highest temperature reached was 102·2°, on the 25th. Progress towards recovery has been slow, owing to the formation of abscesses near the wound, but these are now (July) nearly well, and the patient has gone into the country.

The treatment after the operation was almost *nil*, a spare diet for a few days, an opium pill at bedtime, and ice occasionally. When the abscesses formed they were treated by incision and drainage-tubes.

This is the third operation for umbilical hernia which I have reported in THE LANCET, all successful. I hesitate to speak with confidence from an experience founded on only three cases, but, giving it for what it is worth, I should say that the cases in which it is possible or safe to operate without opening the sac must be very rare, and that the dangers of that proceeding have been a good deal exaggerated, although I would fully acknowledge the special desirability, in this form of hernia, of leaving the sac unopened whenever possible.

Newcastle-on-Tyne.

OVERWORK AS A CAUSE OF INSANITY.

BY GEORGE H. SAVAGE, M.D. LOND.,
ASSISTANT-PHYSICIAN TO BETHLEM HOSPITAL.

As the question of overwork has been raised in the pages of THE LANCET, I have thought it might be of interest to collect some observations made in Bethlem Hospital. It must be premised that the assigned causes of insanity are frequently incorrect, yet at Bethlem we have good opportunities of getting true family histories from the nearest relatives.

Among the men we find many cases in which overwork, especially if associated with worry and money troubles, is the cause of a break-down. Among the women we find very slight evidence of overwork acting as a cause of insanity. Of course there are cases such as those of widows who have to struggle to maintain a large family, but the cases are less common than among the men.

Continuous monotonous work, such as letter-sorting and shorthand-writing, is apt to act injuriously. We have seen cases in which continuous railway travelling acted as a cause of nervous exhaustion. One patient, who has been several times under our care, attributed his symptoms to night work as a "reader" for a daily paper. Diversified mental work never seems to produce the effects that monotonous toil does, unless carried to a great extreme.

I append a few particulars as to the cases attributed to mental overwork that were admitted into Bethlem Hospital during 1874 and up to June, 1875. There were twenty men and eight women.

The ages of the men were as follows:—One under twenty years, nine from twenty to thirty years, five from thirty to forty years, four from forty to fifty years, and one over fifty years. In three only was there a distinct history of insanity in the family; in two others there was at least oddness in other members of the family. The occupations were various; but in all there was a possibility of overwork, which was not clear among the women. There was one belonging to each of the following employments:—Architect, surveyor, accountant, inventor, musician, clergyman, artist, artmaster, schoolmaster, policeman, and bootmaker. There were seven clerks, including two law-writers, and two students: one an Oxford man who had exhausted himself in getting a double first, and the other a medical student preparing for his second College.

In the above cases there were few complications. In one there had been rheumatic fever and chorea; and one, the bootmaker, was distressed by a rupture that interfered with his work. Three were unduly anxious about competition, one about competitive designs, one on account of his pictures being rejected at the Academy, and a third about his "second College." In one only was there a history of drink.

Most had limited incomes that depended solely on their own work. Several owed their exhaustion to following more than one calling; thus one was a librarian all the week and a preacher on Sundays, others worked all day in an office and then did copying at night. Nearly all the cases were admitted in a very weak condition; some refusing food which they fancied they had not earned.

We had every variety of mental disturbance, from acute mania to profound melancholia. I would specially call attention to one series of cases—namely, the general paralytics. We had, among our twenty cases, five suffering from this disease, one of whom sank very rapidly. Besides these we had several cases that caused us considerable doubt as to diagnosis and prognosis. They were admitted weak, tremulous, and with loss of memory, and in some cases buoyant and exalted. They look like general paralytics, but rest and good diet cured them. Another condition was that of self-condemnation. These patients fancied they had not done their duty, and were commonly suicidal. One we learnt afterwards committed suicide.

Among the men one-half were married. This contrasts with the cases we have to consider found among the women.

There were eight women whose friends thought over-study had produced insanity. These were all single; three were under twenty years, two under twenty-five years, two under thirty-five, and one under forty-five. In two only was there known to be a family history of insanity. Three had been hysterical before the attack of insanity, three had suffered from other physical ailments—namely, rheumatic fever, chorea, and uterine disease.

The form of insanity varied. We had several with that exaltation that has been noticed as not uncommon in the insanity of young women. This may be in part due to romantic ideas that were bred of novels.

The occupations were as follows:—Five were teachers, one a school-girl, and two dressmakers. Of the teachers, three were in elementary schools, one an ordinary governess, and one a teacher of music and languages.

In none of these cases among the women could I get evidence that satisfied me that real mental work was the cause of the insanity. In one certainly the attack came on two days after an examination, but this girl had a sister who has been in Bethlem.

To sum up, I would say that overwork rarely, if ever, alone sends us patients on the female side. On the male side we do have a fair number who are really broken down by long hours and monotonous mental toil. I believe the monotony is the chief evil.

It will be seen from the above that heredity does not play a very large part in these cases.

A Mirror
OF
HOSPITAL PRACTICE,
BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum, tum proprias collectas habere, et inter se comparare.—Morgagni *De Sed. et Caus. Morb.*, lib. iv. Prooemium.

GUY'S HOSPITAL.

MEDULLARY SARCOMA OF SPERMATIC CORD AND PELVIS; INTESTINAL OBSTRUCTION; COLOTOMY; TEMPORARY RELIEF; DEATH.

(Under the care of Mr. Bryant.)

In our "Mirror" of the 6th February last (p. 196) we briefly related the early history of the subjoined case. The patient having since died, the following notes, taken by Mr. C. E. Perry, will be interesting.

The patient, a tanner, aged eighteen, was admitted Dec. 10th, 1874, with a hard, cylindrical, tender swelling in the right groin, extending downwards into the scrotum and upwards through the internal ring into the pelvis. Two or three days before the patient was on a pack of skins with his leg across a pole, from which a fellow-workman tried to pull him by dragging at his left leg. After resisting for some time, the patient felt a sudden snap and great pain in the right groin. He continued his work till evening, but when he went to bed he detected a swelling in the right groin, which was very painful. Two days afterwards he was admitted into the hospital.

Dec. 23rd.—The swelling along the spermatic cord had diminished, and was not tender; but a round, firm, and somewhat elastic swelling was detected above the pubes, extending about half way to the umbilicus, appearing just like a distended bladder. He passed his urine freely.

26th.—The swelling had increased, and was of a more solid character, extending more to the right of the middle line than the left, and reaching nearly to the umbilicus. There appeared some deep connexion between it and the swelling of the cord where it dipped into the pelvis. Mr. Bryant made a pelvic examination, and found the whole pelvis filled with a tumour. A catheter was passed, but the withdrawal of a few ounces of urine did not diminish the swelling at all.

Feb. 5th.—An exploratory needle was put in, but no fluid escaped. He strained a good deal in passing his motions, and passed very little at a time. An enema was given, and the bowels were freely opened.

March 2nd.—As the bowels had not been opened for a fortnight, and injections were immediately returned, the obstruction in the bowels being very great, colotomy was decided on, and was accordingly done in the left loin.

4th.—He had passed much flatus through the wound, but no motion. He vomited occasionally. Pulse 100; temperature 99·4°.

5th.—He had several fits during the night, there being twitchings on both sides of the body and face, beginning in the right leg. He was almost unconscious, and only recognised his mother between the fits, but was quite blind. He passed some liquid fæcal matter through the wound, but the following day he appeared more conscious, and had only one fit in the night and one in the morning. He passed much flatus through the wound, and complained of his head. He had no motion, and passed his water involuntarily; sp. gr. 1010, no albumen.

7th.—His sight was somewhat better, and he was quite conscious. His abdomen was less tense, and he had passed some fæces, but the pain in his head and in the lower part of his abdomen continued.

8th.—Pulse 80; temperature 99·5°. An examination of his eyes with the ophthalmoscope failed to detect any abnormality.

17th.—He had passed several motions during the past two or three days through the wound, and seemed very much better.

24th.—He vomited two or three times during the day; he passed 48 fluid ounces of urine, sp. gr. 1008. He was ordered ten grains of bromide of potassium and one drachm of syrup of tolu in water three times a day.

April 7th.—He still vomited first thing in the morning, and after food; he had not passed more than half a pint of urine in twenty-four hours. The abdominal tumour was about the same, very hard and distinctly nodulated, the scrotum also being œdematous.

8th.—He had voided only half an ounce of urine during twenty-four hours. A catheter was passed, but no urine was drawn off. Pulse 144; temperature 102·2°.

9th.—There was a good deal of œdema of the tongue, as well as of the feet and ankles. He had passed no urine at all in the twenty-four hours. He was also drowsy. Pulse 128; temperature 100·5°. About 3 p.m. he passed nine drachms of urine, highly coloured and with thick deposit; specific gravity 1012 (neutral); containing a large quantity of albumen; deposit under microscope, blood, pus, &c.

12th.—Passed a pint and a half of urine; specific gravity 1012; clearer. The bowels were opened twice per rectum. The tongue was not so swollen, but on the under surface on the right side there was a large superficial slough. He vomited at times, but there were no cerebral symptoms. The growth seemed much larger and markedly lobulated, extending towards the opening in the left loin, through which it could be felt.

14th.—The patient seemed in a drowsy condition; pupils were contracted and tongue more inflamed; pulse small, hard, and irregular. During the night following he had several epileptic fits. Passed two pints and a half of urine; specific gravity 1010; clear, light-coloured; little albumen.

16th.—He had no more fits. Passed two pints and a half of urine, containing a large quantity of albumen; specific gravity 1011. Pulse 108; temperature 99·8°.

17th.—He appeared very ill; bleeding from the mouth. Passed eight ounces of urine loaded with albumen; much deposit. Temperature 96°.

18th.—He died about 5 a.m.

Post-mortem appearances from the report of Dr. Goodhart.—Dropsy of scrotum and legs. There was one very small cancerous gland in front of the pericardium, just above the diaphragm. On opening the abdomen, which was remarkably prominent forwards as high as the umbilicus, where it ceased by an almost abrupt ridge, the recti muscles at the lower part had to be cut from the tumour, as they were infiltrated by the latter. The abdominal cavity was occupied by a large, soft, fleshy-looking mass, which appeared at either side to be behind the peritoneum; at all events a membrane was reflected from the wall of the tumour continuous with the peritoneum. In front, across the centre of it, ran a third band of fibrous tissue, which corresponded with the thickened layer of transversalis fascia, midway between the pubes and umbilicus. In the median line the tumour was no longer confined to the extra-peritoneal tissue, but occupied the peritoneal cavity, and there were secondary growths in the peritoneum in the left loin, one large mass, one inch and a half in diameter, immediately above the internal aperture made for Amussat's operation in the left loin. The tumour had pushed the intestines out of its way and occupied the entire pelvis, so that there was no room for anything else in that cavity. The rectum was flattened out and empty behind, though healthy. At the base of the bladder was a large mass of growth, about as large as a fœtal skull, which enveloped the urethra on both sides, and the vas deferens on the right. The ureters, up to the brim of the pelvis, were closely contracted, and only with difficulty could a probe be passed along. Beyond this upwards to the kidney they were tortuous, and of the size of the little finger, not particularly thick, but full of urine. In the right groin was a tubular prolongation of the tumour from the external ring to the internal, where it became blended, but still capable of dissection from the main mass. This prolongation was in the tissues of the cord; and when we consider the history, it seems most probable that here the tumour originated; that thence it started along the vas deferens downwards into the pelvis, and so came to occupy the structures at the base of the bladder, and thence filling up the pelvis, it bulged out into the peritoneal cavity above the sacral promontory. The bladder was quite flattened out and empty, and pushed considerably to the left; its mucous surface was injected in places, but its coats were neither thickened nor otherwise altered. Two secondary tumours were appended to the main one, besides the funicular prolongation already mentioned, one above connected into another growing in an omental adhesion attached to the upper part, and the second near to the left internal ring. The colon was somewhat contracted beyond the opening made for colotomy, but the sigmoid was dilated and contained scybala. Some prolapsus of the colon out of the aperture; all the parts had soundly healed. Round the internal attachments of the bowel to the opening the peritoneum had several tubercles of cancer, and at the upper part was a large mass, as if the cut in this region had determined a growth of cancer here, for there was no reason why the growth should have developed here rather than elsewhere. There was no general carcinoma of the peritoneum. The kidneys were pale, and weighed 15 oz.; they were examples of the fatty style of tubal nephritis. The pelves were very much dilated, the pyramids flattened out and forming cysts, and their mucous surfaces, as well as that of each pelvis, much ecchymosed. The liver contained a large mass, of circular form, distinct from its substance, yellowish externally, very vascular centrally, on the under surface of the right lobe away from the gall-bladder. The spleen had a mass invading its substance. A section of the growth in the pelvis showed it to be a firm yet softish, yellowish, but in parts gelatinous, very vascular growth, which under the microscope appeared to be made up of lymph-like cells. The lumbar glands were cream-like near promontory of sacrum; they were not enlarged further up.

A subsequent examination of a portion of the secondary growth from the liver showed that it was not distinctly sarcomatous; it had the appearance which many growths in the liver have—namely, a very fibrous stroma with alveoli full of rounded cells. The cells were not all round, some of them were angular. The secondary growths, at any rate, must be called carcinoma rather than sarcoma.

GREAT NORTHERN HOSPITAL.

A CASE OF TRAUMATIC EMPHYSEMA WITHOUT INJURY TO THE CHEST-WALLS.

(Under the care of Mr. ADAMS.)

FOR the notes of the following case we are indebted to Neville Hart, M.B., house-surgeon.

C. P——, aged eight, was injured on the 25th of June by the wheel of a light cart which, passed over the upper part of his back. On admission there was intense emphysema of the face, temples, and chest, as well as of the left side of the back, the abdominal walls, arms, and thighs. There was also great dyspnœa. No bruise was apparent, nor were any fractured bones discovered; but the sternum appeared considerably depressed from the greatly distended condition of the areolar tissue of the pectoral muscles and arms. The emphysema and dyspnœa increased until his death, which occurred about an hour and a half after admission.

Autopsy, forty-one hours after death.—Rigor mortis present. No external marks of injury. Frothy fluid mixed with blood was seen issuing from the mouth and nostrils. The emphysema was more or less general. On removing the sternum and costal cartilages a quantity of air escaped from the chest. The lungs were much collapsed; both upper lobes were deeply congested, the lower lobes less so. On the antero-lateral surface of each lung there was a reddened patch, on which some distended, but apparently unruptured, air-cells were seen. The trachea and bronchial tubes contained red, frothy fluid. The heart was nearly empty, and the blood was slightly coagulated. The ribs, costal cartilages, and vertebræ were found uninjured. The abdominal viscera were healthy and uninjured.

This case is of interest as it shows that the lungs may be ruptured, under certain conditions, without great injury to the chest-walls. Mr. Hilton, in a similar case under his care, thought rupture occurred owing to the egress of air from the chest having been prevented. This case certainly favours the view adopted by Mr. Hilton, as the boy's face was probably driven down upon the ground. It is possible in both cases that the endeavour to keep the chest filled to assist in withstanding the pressure, afforded the conditions favourable to rupture.

GENERAL HOSPITAL, BIRMINGHAM.

A CASE OF SYPHILITIC DISEASE OF THE NERVOUS SYSTEM.

(Under the care of Dr. FOSTER.)

FOR the notes of the following interesting case we are indebted to Dr. Alfred H. Carter.

W. W——, aged forty-seven, a brickmaker, was admitted on May 22nd, 1874. The history of his case was as follows. About the end of October, 1873, he, for the first time, complained of burning and aching pain in right temple, associated with tenderness on pressure at the same spot. This pain was much worse at night, so much so that it gave rise to insomnia for several weeks. This condition continued for a week, and then he began "to see double," and the right eye was intolerant to light. On seeking medical advice, he was told that he was suffering from rheumatism of the head, for which he remained under treatment until the end of that year without much relief. During this time his right upper eyelid began to droop. He then left town for the country, and the pain moderated, but the ptosis increased, and the diplopia continued. He remained in this state more or less until the middle of April, 1874, when, in addition to the symptoms already named, he noticed a watery discharge from the right ear, attended with pain in the organ (this preceding the discharge for a few days) and deafness, not complete, but well-marked. This continued for eight or nine days, and then stopped completely, and did not return; with it the deafness also disappeared. Still the ptosis increased, and then diplopia became more marked, until May 1st, when the former was complete. On May 3rd (two days after), at 11 A.M., on attempting to rise from his seat after being shaved, he fell at full length on the floor, as the result of an attack of giddiness. He drank some water, and felt all right again, and nothing unusual in any way did he notice in his limbs at that time. He felt as usual the following day, but thought it better to remain at home. At 4 P.M., on rising from his chair to go up stairs (not feeling so well), he noticed that his left leg dragged after him. He retired to his bed, and the next morning, on waking, found his left arm and leg quite powerless, his mouth drawn to the right side, and his speech impaired. There was not at any time any loss of consciousness. Without any material alteration in his symptoms, he applied to the hospital for admission on the 22nd of that month (three weeks after).

He has been the father of eleven children by the same wife, of whom only four are now living. Of the remainder three were born dead, one had small-pox (syphilitic pemphigus?), and died before three weeks old; one died of scarlet fever (?) at three years of age; and two died before two years of age, causes unknown. No history of syphilis admitted by the patient, who has always had good health until the present illness, with the exception of small-pox when quite young. Knows nothing about his relatives as to the causes of death. His work has exposed him much to wet, standing frequently in water with shoes and stockings off.

At the time of admission his condition was noted briefly as follows:—

May 22nd.—Patient looks strong and well nourished; his right eyelid is completely paralysed, and covers the eye of that side entirely; his mouth is slightly drawn to the right side. On raising the drooping eyelid, a strong convergence of that eye is noticeable, with complete inability to move it either outwards or downwards, and only slightly upwards. The movements of the left eye are perfect. The tongue is protruded in a straight line, and the faucial arches are equal. The ordinary signs of paralysis of the facial nerve are apparent on the left side, but associated with no perversion of sensibility. The left orbicularis palpebrarum acts perfectly. On the opposite side there is numbness of the face, as far inwards as the nose and middle line of upper lip, extending as low as the angle of the mouth. The same condition occurs with regard to the surface of right hard palate. On anything being drawn over these surfaces, a sensation like "pins-and-needles" is complained of. His speech is thick and spluttering, but he has no difficulty in finding words to express his thoughts, but only in articulating them. No mental aberration beyond slight impairment of memory. The left arm hangs perfectly helpless by his side, and he is unable to move it in any direction. The fingers are semiflexed, and the thumb drawn across the palm; no rigidity. He is quite unable to open his hands. The left leg is not so completely paralysed; he is able to stand, and can walk imperfectly by the aid of a stick, but in so doing drags his toes, which frequently catch the ground. Sensation perfect in both upper and lower limbs. Complains of no pain anywhere, and feels "quite well in himself." Physical examination of chest and abdomen reveals no morbid sign. Ordered five grains of iodide of potassium three times a day, and counter-irritation to the right temple, in the shape of a blister, to be kept open by cantharides ointment.

June 20th.—Has much improved. Can now walk about without a stick; begins to move his arm. His speech is better; and the eyelid can be raised high enough to expose the whole of the pupil of the right eye. The strabismus and the numbness remain as usual. Some œdema of the left arm and leg. Ordered to keep the arm in a sling, and the leg to be supported in a horizontal position. Counter-irritation to the temple discontinued. The iodide of potassium to be increased to ten grains three times a day.

Aug. 10th.—Discharged. All the hemiplegia had completely disappeared. The action of the right eyelid perfect, though some strabismus still remained, much less marked, however, than on admission. In excellent health.

Reviews and Notices of Books.

The Cyclopædia of the Practice of Medicine. Edited in German by Dr. H. VON ZIEMSSEN. The English Translation edited by ALBERT H. BUCK, of New York. London: Sampson, Low, and Co.

THE first three volumes of the American translation of Ziemssen's "Cyclopædia of the Practice of Medicine" are before us, and ere making any comment on the first volume we have much pleasure in saying that they promise to be a very valuable addition to medical literature. The more important advances that have been made in Germany no doubt gain slow admission into this country through the pages of this and other periodicals, but we have them here at first hand, many of the articles being written by those whose names have become as household words, and presented to the public in a style commensurate with the magnitude and value of the work. We believe that about eight or ten volumes of the "Cyclopædia" have been published in Germany, and it is stated in the prospectus of the English edition that arrangements have been made by which two or more volumes will be published per annum till the whole is completed. The general scheme of the work is analogous to that of our own recent Cyclopædias of Medicine and of Surgery, each article being entrusted to the care of one who has paid particular attention to it, and the whole work therefore constitutes a series of monographs written by observers possessing special qualifications for their tasks.

The first volume, which we propose to consider here, is devoted to acute infectious diseases. The subjects and the names of the authors are in succession:—(1) Typhoid Fever, by Liebermeister, pp. 1—237. (2) Relapsing Fever, (3) Typhus Fever, and (4) Chorea, by Lebert, pp. 237—464. (5) The Plague, by Liebermeister, pp. 465—487. (6) Yellow Fever, by Haenisch, p. 488—510. (7) Dysentery, by Heubner, pp. 511—573. (8) Epidemic Diphtheria, by Oertel, pp. 574—699. It need hardly be remarked that Ziemssen, who edits the "Cyclopædia," has shown considerable tact in the selection of his contributors.

The account of typhoid fever given by Liebermeister is drawn from his personal experience, embracing 1900 cases which came under his care whilst physician to the Hospital at Basle. He defines the difference between typhoid and typhus fever to be that typhus fever is a purely contagious disease, whilst typhoid belongs to the miasmatic contagious diseases. Typhus can be transmitted directly from person to person; its contagion is as intense and evident as is that of the acute exanthemata. Typhoid fever, on the contrary, is never transmitted from person to person. Of all the cases treated at Basle from 1865 to 1871, only forty-five originated in the hospital, and many of these, there was reason to believe, were due to the formation of local foci of the disease. Liebermeister agrees with Budd in believing that it is propagated continuously, and never originates autochthonously. It does not originate in decomposing substances, but finds in them a favourable ground for its growth and multiplication. It would seem that the period of incubation is on the average three weeks, but it may be as short as two and as long as four. As regards the mode of entrance of the poison into the body, Liebermeister thinks it is certainly by the air breathed, and in all probability, notwithstanding the opposition of Pettenkofer, by the water. In almost all instances, when an outbreak occurs, careful inquiry will show that the typhoid poison has been introduced, and Liebermeister gives some very remarkable evidence on this point. The frequency of cases of typhoid at different seasons of the year is well shown by curves representing the mortality from this cause in Basle, Berlin, and London, comprising about 18,000 cases, and agreeing well with one another. The minimum proves to be in February and April, and the maximum in September and October. In Munich, however, a remarkable exception occurs, the maximum frequency being in February, four months later than in Berlin. This Liebermeister attributes to the breeding-place of the poison being more deeply seated in the earth, since the same isothermal line runs through both cities. Buhl's researches have further shown that as the level of the ground-water steadily rises typhoid diminishes, and as the latter falls the disease increases; and the same holds good for Berlin. The Munich observers, Pettenkofer, Buhl, and others, think the poison does not enter the system by drinking, but by the air. Liebermeister, however, adduces good arguments against this view.

The symptomatology of the disease is very fully yet clearly given, great stress being laid on the importance of thermometric observations, in regard to which he says justly that "a rational treatment of typhoid fever without following the temperature is not possible, and it may well be asserted that any physician who does not make two or more observations of the temperature every day neglects his duty"; and, he continues, "the use of the thermometer in private practice, showing, as it does, to unprofessional persons the importance of the rise and fall of temperature, and the effect of treatment on the fever, has more than anything else narrowed the field of homœopaths and charlatans." As might be expected, the section on the Pathology of the disease is singularly complete, and the reader will find the results of all the more important modern German investigations on this subject, though those of foreign observers are but sparingly alluded to. The section on the Diagnosis of Typhoid Fever, and that on the Complications and Sequelæ of the disease are admirable.

Liebermeister adduces very strong evidence in favour of the cold water treatment, showing that in regard to cases of consolidation of the lungs, of hæmorrhagic infarction, and of pleurisy, a notable diminution both in frequency and mortality is observable since the introduction of the cold water system.

We have given somewhat full details of the subject of typhoid fever, in order to give our readers some idea of the general features of the work, but the other articles are not less completely worked up. This is particularly the case with Lebert's memoirs on Asiatic Cholera and on Typhus Fever, which are replete with interesting information; and the same may be said of Heubner's article on Dysentery. This author seems to be more familiar with English literature than the others.

The paper, the print, and general get-up of these volumes, their size alone excepted, leave nothing to be desired. The translations are exceedingly easy, and we have noticed very few clerical errors. It is a work that we sincerely trust will meet with liberal recognition on the part of the numerous physicians and general practitioners throughout the country who are desirous of making themselves acquainted with the advances that have been made in medicine during the last twenty years in Germany.

Kystes Hydatiques du Poumon et de la Plèvre. Etude Clinique. Par ALFRED WILLIAMS HEARN, Docteur en Médecine de la Faculté de Paris. pp. 250. Paris: Delahaye. 1875.

THIS is a careful and exhaustive monograph on a disease happily rare in this country, but remarkably prevalent in Australia and in Iceland. The author was led to undertake the laborious task of its composition by having had under his care a patient who presented most of the symptoms of tubercular phthisis, but who died somewhat suddenly from asphyxia, after an attack of profuse expectoration of hydatid cysts. In compiling the work, the author has consulted every treatise on the subject and the records of every published case, appending to his monograph a full abstract of 144 cases, 82 of which were fatal. Armed with the data afforded by the study of these cases, he gives a complete analysis of all the symptoms of pulmonary hydatid disease; the diagnosis between these intra-thoracic cysts and tubercular phthisis or pleuritic effusion; the prognosis—which is found to be worse in Europe (two-thirds of the cases being fatal) than in Australia, a difference owing to surgical interference being resorted to in the latter country far more frequently than in the former. Such interference, he thinks, should take place as soon as a diagnosis is made, and should be either puncture or the continuous galvanic current. The following are briefly the symptoms to which he assigns most importance: a spasmodic cough, at first dry, but later accompanied by expectoration, either bronchitic or of hydatid fluid or cysts; dyspnœa in proportion to the development of the cyst; hæmoptysis, at first scanty, later copious, and either slightly preceding or accompanying the rupture of the cyst; persistent pain in the region of the cyst, and frequently a sensation as of a foreign body in the chest; debility contrasting with the healthy appearance of the patient; little or no pyrexia or nocturnal sweats. Locally, the cyst frequently leads to bulging of the chest-wall; diminution or absence of vocal fremitus; dulness limited to the area of the cyst when this is in contact with the thoracic parietes; absence or diminution of breath-sound at the level of the cyst, with puerile or bronchial breathing in its neighbourhood; and lastly, at the end of a variable time, the pathognomonic expectoration of clear and transparent liquid, or of membranes or hooklets. Out of the 62 cases of recovery here recorded, in no fewer than 45 the cure was due to expectoration of the hydatids, while in 1 case they escaped by means of the intestine; 5 got well after simple puncture, and 1 after puncture with injection of iodine into the cyst; 7 followed puncture or incision through the chest-wall and spontaneous evacuation of the cysts by the bronchi; and 2 only resulted from incision through the chest-wall.

OUR LIBRARY TABLE.

The Quarterly Journal of Microscopical Science. Edited by Dr. PAYNE and Messrs. LANKESTER and DYER. No. LIX. July, 1875. London: J. and A. Churchill.—The present number of this journal opens with an interesting paper by Mr. Balfour "On a Comparison of the Early Stages in the Development of Vertebrates," in which the successive modifications undergone by the blastoderm are traced from the amphioxus through the sharks and osseous fishes, frog, and bird, to the mammal. Dr. Denis Macdonald gives an account of the anatomy of the border of the posterior elastic lamina of the cornea, and demonstrates that this lamina does not, as is usually stated, become continuous with the little tendons of the ligamentum iridis pectinatum, though they are associated in a very intricate and peculiar manner. Dr. Klein has a good paper on the pathology of sheep-pox, of which we have elsewhere given an account. Mr. Jackson describes a new peritrichous Infusorian, to which he has given the name of Cyclochæta spongillæ. Mr. Hubrecht supplies some observations on the minute anatomy of Mediterranean Nemerteans. Mr. Lankester records some new points in the structure of amphioxus and their bearing on the morphology of vertebrata. Dr. T. R. Lewis describes certain Nematode Hæmatozoa in the dog which correspond to the Filaria sanguinolenta. Dr. Macintosh finally describes the Amphiporus spectabilis and other nemerteans. There is the usual quarterly chronicle of microscopical science and account of the proceedings of societies. The part is illustrated by five plates, and is a very good one.

The Childhood of Religions; embracing a Simple Account of the Birth and Growth of Myths and Legends. By EDWARD CLODD, F.R.A.S. London: King and Co. 1875.—This book is by the author of that excellent and very popular little volume, "The Childhood of the World." The present subject is one more difficult of treatment, and requires, if we may so express it, more delicate handling. The volume is intended for the youth of both sexes, who must, however, have attained a certain age and a degree of knowledge sufficient to appreciate it; and we can understand that many parents and teachers might hesitate to employ it. For our own part, we hold that in this, as in other things, "honesty is the best policy." If our aim be the attainment of truth, and we pursue it with singleness of purpose, reverently seeking to find out, assimilate, and sympathise with whatever is honest, true, and ennobling, we have no cause to fear, but everything to hope, from our efforts to behold things as they are, and not as they appear by the light of our own prejudices. Apart from these considerations, however, this book will be found uncommonly interesting to grown-up children who have occasionally dipped into the sources of information from which our author has drawn his materials, but who do not possess the time or opportunity to pursue these studies steadily and systematically. To such it will prove, as it has proved to ourselves, most acceptable. The information is well arranged and of the best, and the history of "The Childhood of Religion" is told and traced out simply, lucidly, and sympathetically.

On the Graphical Representation of the Movements of the Chest-wall in Respiration. By A. RANSOME, M.D. Pamphlet. 1875.—In this pamphlet, which is reprinted from the Memoirs of the Literary and Philosophical Society of Manchester, Dr. Ransome, already well-known for much good work in connexion with respiration, describes an instrument by which he has been able to measure and record the movements of points on the chest-wall, in *three* directions at right angles to each other—namely, forward, upward, and outward—during one act of breathing. He shows that the actual shape of the respiratory curve (ends of the third pair of ribs) is very different from what it would be on the usually received hypothesis, that the ribs are simply rigid bars moving upon the support of their costo-vertebral joints. Dr. Ransome gives a series of tracings, in which he shows the true form of curve pursued by the ribs in question, which are deserving of careful study, and may perhaps hereafter become an aid in the clinical investigation of disease.

Zeitschrift für Biologie. BUHL, PETTENKOFER, and VOIT. Band xi., Heft 2. München, 1875.—This part contains a paper by K. Vierordt on Physiological Spectral Analysis. 2. On Asparaginic Acid as a product of Artificial Digestion of Glue by the Pancreatic Gland, by Dr. Knieriem. 3. Researches on the Contamination of Air by Drain-pipes, and upon the Relative Activity of the chief Disinfectants, by Dr. F. Erismann. 4. Xanthin and Uric Acid in the Urine of a Diseased Ram, by H. Weiske. 5. Histological and Physiological Studies, by G. Valentin (construction of magnet-electrometer and action of currents). 6. Substitution of Lime in the Bones, by Dr. J. König. Lastly, On a Means for determining the Presence of Free Carbonic Acid in Water, by Max von Pettenkofer.

Proverbs from Far and Near, Wise Sentences, &c. Collated and Arranged by WILLIAM TEGG. London: William Tegg and Co. 1875.—This is a selection of proverbs, &c., gleaned, as the editor tells us, from the pages of Ray, Fuller, Grose, and many another worthy—some well, others little, known. And what an amount of thought is contained in a small number of pages! The wit, wisdom, and experience of ages are compressed in these pithy sentences, which give expression to almost every variety of character and every shade of thought. Some are rough and graphic, some playful, tender and delicate in expression, some witty, some cold and cynical, many humorous, and many more sagacious. The selection seems to us a good one; and there is something for everybody in a collection of proverbs.

The Monthly Microscopical Journal. Edited by Dr. LAWSON. No. LXXIX., July 1st, 1875. London: Hardwicke.—This number contains four articles:—1. Notes on Bucephalus polymorphus, by Charles Stewart. 2. Measurement of Angular Aperture, by Mr. Stephenson. 3. Notes on the Use of Mr. Wenham's Reflex Illuminator, by Mr. Slack. 4. On Dr. Schumann's Formulæ for Diatom Lines, by Mr. J. Hickie. The Chronicle of the Progress of Microscopical Science contains a good account of Dr. Thin's article on the Microscopic Appearances in Inflammation of Connective Tissue.

ANATOMY AT THE EXHIBITION OF THE ROYAL ACADEMY.

IN the 19th century the portraying of the nude figure does not occupy so much of the artist's attention as it did in those days when art was in its highest state of perfection —in those bright days when men were taught to speak the truth and pay a strict attention to their physical well-being, and when women were so uncivilised as not to interfere with their natural figure by constricting stays and tight waistbands. But with the advance of civilisation the public taste has proceeded with equal steps, so that now such a state of over-refinement has been attained that the visitors at a gallery dare hardly look at a picture of a figure in scanty attire, even if a Hanging Commitee should have ventured to find a place for it upon their walls. Such a state of affairs is much to be regretted, for the human form offers the grandest theme for the painter's art, and the severest test of his scientific knowledge and skill. A mere change in the position of a limb or an alteration in the pose, by bringing into play a fresh series of muscles, whilst it sets another at rest, presents a varying subject to the student in the life-school, just as a passing cloud or a gust of wind unfolds fresh beauties to the admiring eye of the landscape painter. The more drapery that is placed upon the human figure the easier does the artist's task become, and the better opportunity does it afford him for putting on colour. In fact, the model now, for the most part, plays the part of a lay figure, and its subtle beauties are hidden much as the tracery of a church roof or the decoration of a rood-screen was smothered by the plaster and whitewash of the unappreciative churchwarden of the last century.

There are, however, in the exhibition at Burlington House some few pictures to which we may venture to draw the attention of the admirer of the highest form of pictorial art.

"A Modern Cinderella" (64) is a charming little picture, somewhat in the style of the modern French school, and, with the aid of the letter-press of the catalogue, tells a pathetic tale. The patient model has just taken off, and is hanging up, a silk dress which she has been wearing for the artist, and is about to put on her old and well-worn dress. The arms and shoulders are exposed, and though the subject can hardly be considered as an anatomical study, still Mrs. Jopling has shown enough of the nude figure to make a picture-dealer's wife declare that she could never hang such a thing in *her* house. "Ezekiel's Vision" (129) by Mr. Poole, R.A., is one of the most displeasing pictures in the exhibition. It contains some small naked men, which, quoting Ezekiel (i. ver. 5), the artist tells us are "the likenesses of four living creatures." "The Festival," and "The Golden Age" (233 and 236), by E. J. Poynter, A., we count amongst the gems of this year's exhibition. They are hung on either side of the door of the third gallery. They are pure examples of anatomical study. The muscular development of the male figures, who are gathering ripe fruit, is treated in a most masterly manner, and without any of that exaggeration of muscle which Raphael and the old masters were tempted to indulge in.

No. 398, Mr. Leighton's "Eastern Slinger scaring birds in the Harvest Time" (moonrise), comes very near perfection. The picture, which is as strange as it is attractive, demands a careful and lengthy examination. A young man of brick-dust hue is in the act of slinging a large stone. He will have to sling it a long distance, for the birds have not dared to come anywhere near him. Now, considering the expenditure of force which the act must necessitate, we have no hesitation in saying that he is not exerting himself sufficiently. The left arm, which occupies an abducted and unnatural position, should be much closer to the side, and the hand should have been clenched. Such an arrangement would have given much energy to the conception, and by throwing the muscles of the left side of the chest into vigorous action would have imparted into the upper part of the figure a fixity and strength which at present it lacks.

"Andromeda" (473), by A. Hill, is a very graceful figure, soft and slender as an Andromeda should be. Standing upon the wet and slippery rock, she receives almost all her weight upon the left leg; but, altogether, there is a want of security in the pose. Mr. Hill has graced the foot with a second and third toe longer than the great toe; yet, notwithstanding this charm, the drawing of the leg and foot does not please us so much as that of the upper part of the figure.

No. 875 (L. Wingfield) represents a fair young woman weeping by the waters of Babylon. The artist has not been successful in the selection of his model, whom he has painted with bare foot and shoulders. The picture is hung high up in a corner of the lecture-room, where it will not be likely to attract much attention.

In the sculpture galleries Mr. W. C. Marshall, R.A., is well represented by his "Nausicaa" (1326). Mr. E. B. Stevens's "Bowler" (1323) is a fine and powerful study. Mr. J. Warrington Wood has two fine works in marble in the central hall.

THE LANCET.

LONDON: SATURDAY, JULY 24, 1875.

When the Obstetrical Society took up the subject of Puerperal Fever for discussion, they were met at the very outset by the preliminary question: Is there such a thing as puerperal fever? It is well to begin at the beginning—to take nothing for granted. The question was framed, as Dr. Arthur Farre showed, in a remarkably able argument, syllogistically, almost precluding any other than a negative solution. Mr. Spencer Wells took the definition of puerperal fever adopted in the Nomenclature of the College of Physicians drawn up by Dr. Farre: "A continued fever, communicable by contagion, occurring in connexion with childbirth, and often associated with extensive local lesions, especially of the uterine system." Upon this theme Mr. Wells says: "I must ask you to say if, in your experience, you ever saw such a case which could not, on careful inquiry, be traced to exposure of the patient to some one or other of the contagious or infectious fevers—to scarlet fever or diphtheria, to measles or small-pox; and I proceed to ask you if, in any case where puerperal fever could not be proved to be really scarlet fever, diphtheria, measles, or small-pox, ... it was not a traumatic or surgical fever, erysipelas, pyæmia, or septicæmia."

Now, the first thing that occurs to the medical reasoner on studying this complex question is, to refuse to be bound down within the precise limits assigned. On its own hypothesis, indeed, the question is imperfect. Typhoid, for example, is omitted; and yet it is certain that it may attack lying-in women, and that its specific characters may be so obscured by the special conditions of the recipient as to simulate what is conventionally called "puerperal fever." Then follows a more serious fallacy in the argument. Mr. Wells pursues his point thus: "If you have seen such a case, then let us know something about the fever, its period of latency, its course and duration, and its termination; and especially tell us something about the poison which has been the cause of the fever." Now, this interrogative argument bears a very close resemblance to the *petitio principii*. It would not follow, as is here assumed, that a specific puerperal fever does not exist because those who believe they have seen it cannot define its period of latency, its duration, describe its pathology, and especially say something about the poison. On this mode of reasoning there was a time, and that not very remote, when we should have been called upon to deny the existence of typhoid fever. And even now, although we may "say something about the typhoid poison," we cannot be sure that that "something" is worth saying.

Dr. Fordyce Barker very aptly and clearly showed that Mr. Wells, in asking for this specific account of the pathology of puerperal fever, was asking for more than was granted as known of the zymotic fevers. "Would," he said, "Sir William Jenner or Dr. Murchison, or Hoffman or Lebert, insist that a disease could not be registered as typhus or relapsing fever except certain anatomical lesions could be demonstrated?"

Then, again, there is another fallacy in the proviso—"on careful inquiry." It seems to be implied by the terms and structure of the question that the "inquiry" which should fail to trace a presumed puerperal fever to scarlet fever or other known zymotic, or to the conditions that may for convenience be included under the general term "surgical," could not be "careful." Now, it may be freely admitted that careful inquiry will frequently bring to light the fact that what has passed for puerperal fever was really a zymotic fever introduced into a lying-in woman. But it must also be admitted that the most careful inquiry will not seldom fail to elicit any evidence to justify this suspicion of zymotic invasion. And yet the patient is stricken with a terrible, even fatal, disease.

Grant this—and how can it be denied?—and then we are brought face to face with the practical difficulty. What shall we call this disease which kills? Shall we, because we cannot discover in a given case that it is scarlet fever, or measles, or pyæmia, or erysipelas, say it is not a fever at all? Yet that is really the *reductio ad absurdum* prepared for those who assume that all fevers in lying-in women must be scarlet fever or some other of the known diseases enumerated in the question. This assumption would land the physician in perpetual difficulty. For example, "careful inquiry" will often not be successful in tracing the source and nature of the fever until long after the patient is dead. What is he to call the fever in the meantime? How will he register the cause of death? There must, then, for practical purposes be some conventional or provisional name which shall embrace all the febrile conditions to which the lying-in woman is liable. What name so convenient as "puerperal fever"?—one consecrated by custom, and possessing the inestimable advantage of not committing the physician to any absolute theory? Struggle as you may, prove to demonstration that there is no such entity as puerperal fever, this or some equivalent general term will be imposed upon you by the irresistible logic of facts. Nor will it help us much to adopt Dr. Farre's term, "post-partum fever." This is only shifting the difficulty. Very soon the same terrors that in the popular mind are attached to the term "puerperal fever" would gather around "post-partum fever." Nor is the term really so good. It is less comprehensive. Whether it be in strict etymological correctness or not, the word "puerperal" is understood to embrace the fevers that manifest themselves shortly before and during labour. These the word "post-partum" ignores.

It is a curious illustration of the influence which the syllogistic form of putting a string of questions exercises in dictating the answer, that many of the speakers fell into the "surgical trap." There was quite a chorus of assent to the proposition that there was no such thing as puerperal fever. The chief dissentients were Drs. Barnes, Fordyce Barker, and West. These speakers, as well as Dr. Richardson, all insisted upon the peculiar condition of the body brought about by the processes of labour and puerpery, and the consequent liability to fever as the outcome of disturbed puerperal process. Some of these forms of disease were described in this journal some years ago by Dr. Barnes in a series of lectures on Puerperal Fever, under the names "excretory puerperal fever," "thrombotic puerperal fever," and others. In those lectures he justified the term "puerperal fever" as a general one, meaning in its broad sense simply fever in a lying-in woman. He contended that we must first recognise the bare clinical fact that a lying-in woman has a fever; and that, as the next step, you may proceed to determine, if you can, the precise nature of that fever. Analysis, the search after causes, are subsequent steps. Starting from this basis, he divided puerperal fever into the two great divisions of Heterogenetic, or those derived from without, including the zymotic fevers; and Autogenetic, or those arising from conditions inherent in the patient. This classification and the terms which express it have been adopted by many writers since. It is founded upon unquestionable truths, and seems to offer the best basis for further analysis and inquiry.

A great practical question, one continually surging up, received attention and some useful illustration. This is the question of the contagiousness of puerperal fever. Obviously, the answer will hang upon the conclusion arrived at as to what puerperal fever is. If it be scarlatina, then certainly it is contagious. But Dr. FORDYCE BARKER, who contended so ably for an essential puerperal fever, maintains that surgical septicæmia and surgical pyæmia, occurring in puerperal women, do not constitute a continued fever communicable by contagion. Hence there are puerperal fevers which are contagious, and there are puerperal fevers which are not so. It might be stated generally, bearing in mind that the rule is not absolute, that the heterogenetic class contains the contagious forms, and that the autogenetic forms include those which are not contagious. The great point to remember is that puerperal fever is not a constant entity; that it may be one thing or another distinct thing; and that it may therefore present various characters. In the presence of this difficulty and of the unsettled opinions upon the whole subject, it becomes simply impossible and absurd to lend any countenance to the popular belief that puerperal fever is a disease always communicated to the patient. As we have said in a former article on this point, one case of puerperal fever may occur in any man's practice, and he may be quite innocent of its production. It may be of spontaneous or autogenetic origin. But, as a rule—to which, however, there may be exceptions,—two or a larger series of cases ought not to occur in the practice of one man. In such an event the suspicion that he has been concerned in carrying the disease assumes a high probability, rising with the accumulation of the cases. And, we repeat emphatically, a man in such a position ought to retire for a while from obstetric practice.

But an allied question to the foregoing admits of a more doubtful answer. Is the lying-in woman or the pregnant woman in such a condition of increased susceptibility to the invasion of zymotic poisons that it is dangerous for a physician who has recently been in attendance on cases of scarlet fever or erysipelas to treat such a woman, or to attend her in labour? The answers from good observers are far from uniform. It is a wide-spread belief that there is increased susceptibility. On the other hand, there are not wanting men with ample opportunities of observation who deny it. And if it were true to the extent some think, few women could escape puerperal fever in some form. For it may be affirmed that the risk is being continually run, under the exigencies of daily practice, without any such result as that which is dreaded. Dr. WALLACE mentioned a fact which many men in busy practice might parallel. "On several occasions," he says, "children with the rash of scarlatina out on them were in bed with the mothers when they were confined." This part of the subject clearly needs further study. We have heard a very experienced and thoughtful physician, who was unable to take part in the debate, declare, as his opinion, that pregnancy conferred a degree of immunity from other diseases, including zymotics. Certainly, if the theory of increased susceptibility is carried to the full extent of its logical conclusion, practice could hardly go on. Women must deliver themselves. And most assuredly even then they would not be secure against puerperal fever.

For originality, for extent of material, for ability in handling, this discussion at our London Society will hardly take rank with the famous debate at the French Academy of Medicine some years ago. The difference in the character of the two debates depends mainly upon two circumstances that could not fail to make their mark. The first is that the mass of experience is vastly greater in Paris than in London. Puerperal fever at various times has literally decimated the Paris lying-in wards. The second condition lies in the greater number of physicians whose duties compelled them to observe the disease. Puerperal diseases are not in Paris the exclusive domain of purely obstetric physicians. Hence such men as CRUVEILHIER, ANDRAL, and TROUSSEAU could all bring the wealth of their knowledge of general pathology and their powerful intellects to bear upon the elucidation of the problems presented by fevers in puerperal women. It is true that, in the Obstetrical Society, three surgeons of mark—SPENCER WELLS (who started the theme), HUTCHINSON, and CALLENDER—were drawn into the discussion. But, valuable as their contributions undoubtedly were, it must be admitted that they spoke from little or no personal observation of disease in childbed. Running along a parallel road, they sought to solve a problem that lay beyond their path by the treacherous method of analogy. They reasoned from that which they knew to what they did not know. Analogy, where the fundamental factors are essentially different, requires to be applied with extreme reserve.

This, then, we think, is the weak point of the debate. The experience was too special; too restricted to a section. The debate would have been more valuable if it had elicited and brought into one focus more of the experience and of the matured thought of the many able general practitioners who are familiar with disease in all its forms and every variety of condition. This defect may still be supplied. There is no reason why this debate should not be supplemented by the record of carefully investigated local epidemics or series of cases, or even isolated cases, arising under circumstances that admit of precise analysis and estimation in their bearing on cause, nature, and treatment. The fatal tendency of most minds is to frame theories upon their own limited experience, and to adopt hastily and to adhere obstinately to the theories of others. Yet this is precisely one of those questions which no man can decide upon his own experience. He who would arrive at a just and comprehensive theory must weigh with respect the facts, if not the opinions, of others. With caution he must endeavour to seize their true relations. Then he may gather them into groups that admit of being more conveniently handled. And thus, by a process, tedious perhaps, but trustworthy, he may succeed in analysing the confused elements of a chaos, surveying them separately, and then reuniting them into an orderly whole, where, each retaining its individual significance, all shall contribute, by mutual reflection, to bring out the essential truth.

The London debate may be said, in one sense, to be the complement of the Paris debate. The one gives the history of the puerperal fevers of hospitals, those factories of childbed disease; the other gives the fevers of home life. Both are necessary to the formation of just conclusions. And yet our facts are probably defective. It may still be wise to wait for fresh material. Will the final, the solving evidence come from the bedside or the laboratory? Hitherto the chemist pure has done little. Will the man who combines chemistry with a profound knowledge of histology and the changes wrought in the body by disease, aided by experimental inquiries, do more? There is greater hope in this direction. In the meantime the clinical physician will not be tempted out of his path by the golden promise of bacteria.

◆

THE known relations between dipsomania and other forms of mental disease—their coincidence in both individuals and families, their common origin, their similar characteristics, and allied course—furnish one argument of great cogency in favour of the compulsory seclusion of the dipsomaniac. The condition is unquestionably the result and the evidence of moral imbecility, and in many cases is associated, as distinctly, with mental weakness. It may be doubted whether there are not some forms of insanity which are nearer health than the state of the individual whose craving for alcohol overpowers every other consideration and every motive which can be placed before him. Compulsory restraint is as necessary for the recovery of the habitual drunkard as for that of the insane; and a degree of success may reasonably be anticipated as great as, and indeed greater than, in many other classes of mental disorder. This being so, the full justification for the mode of treatment is to be found in the fact that the relation of individual to society does not differ, even in degree, in the two cases. We shut up our lunatic, not only because the seclusion is essential to his restoration to health, but also because his unrestrained presence in the community is dangerous to its members; and as a source of crime and of injury to others there is little to choose between the two forms of disorder. It is true a comparison is not easy. Lunatics are restrained, dipsomaniacs are not; and so the enormous amount of injury inflicted by the latter on those around them cannot properly be compared with that which results from the acts of the insane. But if a hundred insane persons of various kinds, and a hundred habitual drunkards, were living in their own homes, it is probable that at the end of a year the resulting injury to those by whom each set of persons was surrounded would be much greater in the case of the dipsomaniacs than in that of the insane.

This relation of the drunkard to society, too often overlooked or underrated in our unhappy familiarity with it, furnishes an effectual reply to the objection which has been made to the proposed legislation on the ground that it would involve an unjustifiable interference with individual liberty. Our social life, it has been urged, is so arranged as to secure the most perfect freedom of individual action—a freedom which is to be limited only when its exercise interferes seriously with the well-being of others. Then society may step in with whatever means are best calculated to restrain the prejudicial course of action. All injurious effects on society do not justify the restraint of individual action. Many contingent injuries society is content to endure for the sake of the greater good of human freedom. At present the line is drawn so as to exclude all forms of drunkenness from those actions which justify interference, even temporary, with individual freedom of action. In doing this, however, the disastrous consequences, direct and indirect, to society of habitual intoxication are to a great extent ignored, and yet they are grave and extensive beyond those of many actions which are held to furnish abundant ground for individual restraint.

A reason of great weight for the compulsory treatment of drunkards is furnished by the manner in which intoxication is regarded by our criminal law. While the most constant habitual drunkenness is not considered to be ground for even a temporary interference with individual liberty; while absolute freedom to drink to maddening excess is allowed to every member of the community,—for every criminal action performed under the influence of drink we hold a person criminally responsible. If the drunkard, while under alcoholic influence, not only unaware of the difference between right and wrong, but even unconscious of what he is doing, strike a fatal blow, he is, or may be, liable to the punishment of death. The punishment for the crime is really a punishment for the drunkenness; for it is in most cases merely a matter of external and accidental occasion whether a drunken person does or does not commit a crime. It is hard to justify this severity of the system which in effect visits the drunkenness with the full punishment of the crime, if no attempt is made at preventive measures for the reclamation of the unhappy drunkard, because such a measure would involve a temporary interference with his legitimate freedom.

There is yet another ground on which, it may be not unfairly urged, the liberty of the individual may be reasonably limited if essential for his reclamation from such a curse as that of habitual intoxication. That there are some necessary limits to freedom of action, even where the action involves no injury, direct, or it may be indirect, to any person except the individual concerned, is clearly recognised in our present law. Preservation of nominal liberty may entail the loss of a much more real freedom of action. Accordingly, on some of these actions a restraint is placed. No person, for instance, is at liberty to commit suicide; an attempt at self-destruction is punished as a crime; the survivor of two persons who agree on a common suicide is regarded as a murderer. In the same way, no individual is allowed to abrogate for life his personal liberty; he may not sell his freedom of action, or place his services for the rest of his life at the disposal of another. The liberty to renounce his freedom is denied him, for the manifest reason that such liberty is liberty only in semblance. For the preservation of his real freedom it is necessary that he should be subjected to a definite restraint. The application of this principle to the dipsomaniac is clear. If a man is and apparently cannot help being constantly drunk, unable to discharge the commonest duties of life, private or public, to his family or to society, by continuing free to drink, he does, in effect, forfeit so much larger a freedom of action that his compulsory seclusion for a time, if his cure can be thereby effected, is more than justifiable, it is even obligatory upon society. We hear much nowadays about individual freedom and personal liberty. It is incumbent upon us to look well that we are not losing the substance in grasping at its shadow.

Of course the proposed system is not to be carried into effect without an extensive organisation and fresh machinery. Reformatories must be established; commissioners must be appointed, under whose direction and supervision the system can be worked; the degree of drunkenness at which the seclusion should be adopted must be defined, due safeguards against abuse must be provided, and the power to be allotted respectively to the friends of the individual and to the governmental body must be accurately prescribed. The arrangement of such a system is unquestionably a task of magnitude, but it presents no insuperable difficulty. Systems of far greater elaboration have grown up in our midst with insensible gradations, and the problem needs only due care and perseverance for its successful working out. One thing, however, is certain. Arrangements for the treatment of drunkards must be independent of any existing organisation. The drunkard must not be stigmatised, or be in any accidental way liable to be stigmatised, as criminal or insane. Such an absolute distinction is necessary in justice to the individual, and it is necessary for any prospect of success in the proposed legislation. Safeguards against abuse would not be difficult to frame. In spite of abstract objections of theoretical philosophers, the system of our lunacy arrangements leaves little room for injustice; and the task to provide all due safeguards against injustice would be still more easy in the case of the dipsomaniac than in that of the insane.

◆

We must congratulate the officers of the Army Medical Department, especially the junior ones, upon having their case at last brought before Parliament, as also upon the fact of their advocate being none other than the honourable member for Salisbury.

The report of the debate given in the daily papers was remarkably meagre; it afforded but a skeleton, and that a very imperfect one, of the statement made by Dr. Lush, who spoke with great lucidity and with a temperance that evidently carried weight. No one reading the published accounts of the debate could form anything like a fair estimate of what was said, for instead of confining his remarks to the points that have appeared, Dr. Lush went into the subject as fully as could well be done in a speech of thirty-five minutes' duration, and those of our readers who were not present must refer to Hansard for what was said. Dr. Lush was well supported by other speakers who took part in the debate. After having been present in the House of Commons, we had the curiosity to compare what we had heard with the published reports. If we had depended upon the latter, we should have regarded it as a very poor and weak debate, which it was not. While we think that the medical profession, and medical officers especially, are much indebted to Dr. Lush for his able and disinterested advocacy, we cannot help reminding them that Mr. Lyon Playfair's name was conspicuous by its absence, and this fact should not be lost sight of by the medical graduates of the Universities of Edinburgh and St. Andrews. The least that this right honourable gentleman could have done was to have lent the weight of his name to such a cause on such an occasion, the more especially as he owes his election in a large measure to the votes of the medical graduates of the Universities he represents in Parliament, and he mainly grounded his claim to their confidence and support on his declared sympathy with their professional aims. Though Dr. Lush referred to the subject of honours and rewards, the points principally dwelt on by him were those which the most thoughtful members of the Department agree upon considering their chief grievances, namely—1. The want of a healthy flow of promotion right through the Department. 2. The state of uncertainty in which, as regards their position and everything affecting them, medical officers exist. 3. The arbitrary and harsh manner in which they were removed from their regiments. 4. The withdrawal of forage, which had been guaranteed them by a Royal Warrant. 5. The great difficulty about obtaining a fair amount of leave. And he strongly urged upon the War Minister the advisability of enforcing compulsory retirement from the administrative grade at sixty years, with a view to remedy the first and chief cause of complaint amongst the junior officers. In this he was warmly seconded by Dr. Ward, who, in a clear and convincing manner, showed the necessity of such a step. It seems to us that the view of the matter taken by Dr. Ward is but the common sense one when he remarked that "if control officers, chaplains, and naval medical officers are retired at sixty, surely army medical officers should also be compelled to go at that age." Mr. Hardy's rejoinder on this point, that the services of valuable officers would be lost to the State were this advice carried out, and injustice inflicted on the Department itself, seems to us to be merely begging the question. The Army Medical, like other services, requires young blood, and it seems to us as clear as that two and two make four, that, so far from proving an injury to the Department, forced retirement at sixty years would, while it merely inconvenienced *one*, benefit *three*, two by promotion and one by appointment. We hope the hollowness of the term "rank," as applied to medical officers, has been once and for ever exposed by Dr. Ward, who briefly explained that medical officers *really* possess no rank whatever; nor did they desire vacuum, but substance. That as regards the latter, notwithstanding the fact that their pay of late years was slightly increased, nevertheless, owing to the length of time spent by them in their junior grade, less money was actually received by them during their service than by those for whose benefit the Warrant of 1858 was deemed necessary; and that, as regards the former, it is simply absurd to institute a comparison at all between the relative positions of medical and military officers; for, whereas the former bring an expensively acquired profession, which they sell to the State for *money* only, taking away with them no collateral advantages of title or position, but relinquishing as they began, Dr. So-and-so, the latter come to the State to acquire a profession, plus permanent rank and social standing, to say nothing of a fair prospect of obtaining one of the many lucrative appointments open to combatants.

Mr. CAMPBELL-BANNERMAN, when he stated that a committee composed of eminent medical officers had inquired into the whole question before the late Warrant was issued, omitted to inform the House what committee he was referring to. And he altogether neglected to state how far that Warrant was in accordance with or in direct opposition to the views expressed by these eminent medical officers. Assuming that the principle of unification is sound and correct, which we believe, much surely depends on the way in which a thing is done. It makes all the difference whether you give a copper to a beggar or heave it at his head.

There were fifty members present in the House during the debate, and that Dr. LUSH's speech and those of the other members must have had a considerable effect is clear from the fact that Mr. HARDY begged the honourable member not to divide the House on his motion. And, what is more to the point, Mr. HARDY, as it seemed to us, practically promised to do nearly all that Dr. LUSH asked, in order to avoid a division.

◆

THE current number of the *Quarterly Journal of Microscopical Science* contains an important article by Dr. KLEIN on the Pathology of Sheep-pox, to which we desire to direct the attention of our readers, since the results of his researches throw much light on the closely allied conditions of small-pox in man. The ovine disease, though not communicable to the human subject, is yet due to a specific contagion, and both in its pathology and symptomatology closely resembles variola.

Dr. KLEIN states that, in order to obtain the material for this investigation, he communicated the disease by inoculation to a number of sheep, and thus obtained specimens of skin, which he proceeded to examine with the microscope at all stages of its development. The virus was obtained from two sources; one portion being forwarded by Professor CHAUVEAU, of Lyons, and the other by Professor COHN, of Breslau. In some of the inoculations the lymph was first diluted with from fifteen to twenty times its volume of half-per-cent. solution of common salt, whilst in others it was injected in an undiluted state; but no difference was observed in the two series of cases. A difficulty arose at this point, for it was found that, as in vaccination, it is extremely rare to meet with instances in which secondary pustules present themselves in addition to the primary one at the seat of insertion; but it was felt that the value of the results would be impaired if the investigation were limited to the local effects produced by inoculation. Dr. KLEIN, after some consideration, fortunately succeeded completely in producing a general eruption by introducing the sheep-pox virus into the circulating blood. He diluted the liquid with from fifteen to twenty times its bulk of the dilute solution of common salt above referred to, and injected it directly into the external mammary vein of a healthy sheep. He also inoculated the animal in the ordinary way, and was thus enabled to compare the anatomical characters of the primary and secondary eruptions in the same animal. The injection and inoculation were performed on the 1st of April. The primary papules made their appearance on the 4th. On the 7th several small secondary papules appeared on the lips and around the mouth, and increased rapidly during the three succeeding days.

Careful examination, under high powers, of the lymph sent by Professor COHN revealed several distinct morphological elements—as granules in transparent masses, spheroidal bodies, micrococci, decolourised blood-corpuscles, and bacteria. On exposing the lymph to the temperature of incubation for twenty-four hours, the transparent masses containing granules were found to have developed a kind of mycelium, to the felt fibres of which the granules were attached in rows. After forty-eight hours the granules had developed into micrococci and pale spheroids. These spheroids, which are highly refractive, he considers to be characteristic of sheep-pox in its active condition.

Anatomical investigation of the changes which occur at the seat of inoculation—and those observable in the secondary pustules are essentially similar—shows that they may be divided into three stages: of which the first is characterised by progressive thickening of the integument over a rapidly-increasing but well-defined area; the second by the formation in the rete Malpighii of vesicular cavities containing clear liquid (the "cells" of older authors), in which sooner or later organic vegetable forms are developed; and the third by the impletion of these cavities with pus-corpuscles. The process commences in the rete Malpighii and in the subjacent papillary layer of the corium: in the former by the enlargement of the cells and multiplication of the nuclei; in the latter by the enlargement of the papillæ and the germination of the endothelium of the capillaries. The lymphatic canaliculi become dilated and more distinct, the cells lining them enlarged, and white corpuscles are mingled with their contents; the lymphatic vessels into which they open are distended with a material which resembles coagulated plasma. At about the third day the lymphatics begin to contain granular matter, micrococci, and branched filaments; and by the fifth day they are filled with these bodies. The branched filaments, continuing their growth, form necklace terminal processes, each of which breaks off at its free end into conidia. Whilst these changes are going on in the corium, horny transformation of the middle layer of the rete Malpighii occurs, so that a stratum is formed, and the cells beneath this enlarge and encroach in the form of processes on the subjacent corium, and some of them enlarge into vesicles, whilst others become flattened and form septa between them. The vesicles increase in size and number, and become filled with the felt-like mycelium, the fibres of which are of extreme tenuity, and with micrococci and conidia. Sooner or later, so much of the rete Malpighii as lies between the horny striatum and the papillæ of the corium becomes infiltrated with migratory lymph-corpuscles, which soon make their way into the "cells" or cavities, and convert them into microscopical collections of pus-corpuscles.

No comment is needed to point out the value of these observations and the extreme interest that attaches to them; if any were requisite, it would only be necessary to refer to the article on Small-pox by CURSCHMANN in the second volume of the American edition of ZIEMSSEN's Cyclopædia to show how uncertain is the note there struck on this very point. Dr. KLEIN's observations constitute, in our opinion, one of the best bits of pathological work that has been lately done, and affords strong evidence of the parasitic fungoid origin of the disease.

Annotations.

"Ne quid nimis."

THE ROYAL COLLEGE OF SURGEONS.

THE publication of a Report on the Affairs of the College of Surgeons, drawn up by the President himself, is an encouraging fact. By those who have been conversant with the internal workings of the College for the last twenty years such a contingency must at one time have been deemed almost beyond the range of possibility. Even five years ago, when the fellows and members held their first official meeting within the College walls, the wily and distrustful authorities of that day did not scruple to insult their constituents by causing the resident porter to be sworn in as a special constable "to prevent felonies and disorders." Happily the domination of cliquism is broken, and the light of liberality and of progress has, at last, dawned on the Council of the Royal College of Surgeons of England. If we consider who they are that have been elected members of the Council during the last seven or eight years, we can easily understand that the influence for good of such men must make itself felt. It is not, perhaps, too much to say that if it had not been for the obstructive interference of the nyctalopic officials, who seemed to suffer actual personal pain whenever the transactions of the Council were viewed in the open day of criticism, annual reports from the presidents would doubtless have been instituted long before the year 1875. Be this as it may, the thing is now accomplished, and the fellows and members of the College, while congratulating themselves on the demolition of another barrier of bigoted conservatism, should not forget that to Mr. Marshall is due the credit of the initiation of this Report, and to Mr. Le Gros Clark, the ex-president, belongs the honour of first giving effect to the wise and liberal measure.

The Report itself is of extreme interest, and deserving of attentive perusal. After dealing with the changes in the Council and with other matters concerning the general management of the College, its museum and library, and its examinations, the President, who is singly responsible, proceeds to give an abstract of the Minutes of the Council during the collegiate year. The chief topics therein treated are, firstly, the appointment of a committee to consider and report on the new bye-laws relating to examiners and examinations in anatomy and physiology; and, secondly, the part that the College has taken in the Conjoint Scheme. Although the report of the committee has not yet been presented, the Council has determined that it is expedient that the examinations in anatomy and physiology should be conducted by a board distinct from the Court of Examiners which has charge of the final or pass examination in surgery and pathology. Such an arrangement will not, however, necessarily preclude the examiners in the final examination from taking part in that on anatomy and physiology. It is needless to point out that the separation of the examiners will be fraught with good results. By such an arrangement the examinations at the College will not only become more searching, but, what is of no less importance, they will be more certain and reliable.

The College has for some time past been at a standstill with respect to the Conjoint Scheme; and although the "Enabling Bill" is now passed, there are many shoals and quicksands beyond. The old grievance concerning the appointment of examiners still remains undetermined, and, as far as the co-operating bodies themselves are concerned, is perhaps undeterminable.

MORTALITY RETURNS IN ST. GEORGE'S, HANOVER-SQUARE.

IT transpired at the last ordinary fortnightly meeting of the vestry of St. George, Hanover-square, that this is now one of the few sanitary authorities of the metropolis that persist in their refusal to pay for the copies of the death-register which are so essential to the due performance of the duties of the medical officer of health. This and a few other of the London vestries continue to incur the grave responsibility of endangering the sanitary welfare of their districts, either in the exercise of a paltry economy, or to indulge a feeling of pique at having been called upon to pay the local registrars for services which had been gratuitous during a long series of years, but for which a recent Act of Parliament authorises a legal payment. It is now more than twelve months since notice was given by the Registrar-General that after the 1st of January last, when the new Registration Act came into operation, he should be obliged, in the interest of the metropolitan registrars, to discontinue the transmission of gratuitous returns. Since the beginning of the year most of the vestries have made arrangements with the local registrars by which, at a trifling cost, the sanitary interests of the different districts have been considerably forwarded. Under the new system, these copies of the death-register are in the hands of the medical officer of health each Monday morning instead of Wednesday evening or Thursday morning, as under the old gratuitous system. Beyond this, many of the medical officers of health have arranged with the registrars for *daily* notice by post-card of the registration of every death from zymotic disease. The advantage of such prompt notice in these cases, in order to afford the means for securing as far as possible isolation and disinfection, is self-evident. This was impossible under the old system. The sanitary authority of St. George, Hanover-square, and a few others, continue to ignore all these advantages, and have, in the face of an increasing epidemic of scarlet fever, which renders the mortality returns doubly valuable, wasted more than six months in the vain endeavour to bring about a return to the gratuitous system. The President of the Local Government Board has been importuned by several deputations to urge the Registrar-General to desist from his determination to obtain for his *employés* a payment which has been legalised by Act of Parliament, and which constitutes a small but perfectly legitimate portion of the expenses incidental to sanitary organisation. At the meeting of the St. George's vestry before referred to, General Sir William Codrington pertinently remarked that the returns would cost only £25 a year, and that it would be better to pay for them, and know what was going on; but this common-sense view did not prevail, and a resolution was passed to make another application to the President of the Local Government Board. In the meantime there are no mortality returns for the use of the medical officer of health of the district of St. George, Hanover-square.

THE NARCOTIC INFLUENCE OF RAILWAY TRAVELLING.

There is something peculiarly striking in the somnolence which the movement of a railway carriage induces in a large number of travellers. It is not felt by all; some persons, indeed, are quite unable to sleep in a train; but the sedative effect on a great many is quite irresistible. In these days of railway catastrophes, the timid traveller, possessing a strong imagination—an essential element in great timidity,—might weave a curious fancy of a syren lulling to sleep the victims whom she lures to destruction, or of grimy-handed Art imitating the redder touch of Nature in the unconsciousness to pain into which, as Livingstone has taught us, the victims of the carnivora pass before their death. But to the physiologist the phenomenon has a scientific interest as another illustration of the strange effect of reiterated sound upon the brain-cells; gently loosening, by its vibrations, the links which bind together the centres of consciousness and of sensation. We know of many instances of a similar effect on the nerve-centres of repeated sensory impressions. How they act we do not know yet, but we have gained some insight in the discovery of the part which "inhibition" plays in nervous action. We see it, for instance, in many effects of peculiar auditory sensations. Take the influence of the ploughboy's whistle on his resting team, or the idiosyncrasy to the sound of the bagpipe, with which Shakspeare has made us familiar. We know still less of the mode of the action of sound upon the brain to which we have referred: whether on the nerve-cells directly or through the vessels, whether through the auditory path or through many sensory nerves, or whether in part by the motion of the brain itself upon its "hydrostatic bed," is still uncertain. In any case it is a rough reproduction of the "lullaby" which is the instinctive sedative of nature, and doubtless may be allowed to exercise its full effect with much advantage in lessening the wearying effects on the nerve-centres of a railway journey.

THE CHOLERA.

Hardly have we had a breathing-space since the cessation of the last great epidemic of cholera in Europe when the disease has again shown itself within the basin of the Mediterranean. Some time in May last, cholera, it would appear, broke out in Hamah, a city of Syria, having a population of about 30,000, and situated midway between Aleppo and Damascus. So much is this city out of the way of the ordinary tracks along which cholera has been accustomed to spread in its westward extensions, that the local medical practitioners and sanitary agents of the Ottoman Government could hardly persuade themselves that the disease was what it seemed to be. Their doubts, however, have unhappily been too certainly set at rest by the dispersion of the disease to Aleppo and intermediate places in the north, to Damascus in the south, and to more than one of the seaport towns. Moreover, in Damascus the disease threatens a formidable development, if, indeed, this has not already taken place. This outbreak has followed upon much distemperature of season, intense and unaccustomed heat in Hamah, and excessive rains in Damascus. Among the early victims to the disease, we regret to have to mention Dr. Dillon, the Ottoman sanitary physician at Mosal, who was directed to proceed to Hamah and report on the outbreak. He was attacked with cholera shortly after reaching that city, and died after a very brief illness.

No definite information has yet been received of the source of the outbreak. It has been stated that the disease was introduced into Hamah by a body of troops coming from Kerbela. This statement requires to be confirmed, but it is by no means improbable. In 1871 it will be remembered that a body of pilgrims carried the disease from Meshed Ali, the sister city of Kerbela, on the Lower Euphrates, across Arabia into the Hedjaz, whence it spread into the Soudan. The existence of the disease in Meshed Ali had not been noted until after the appearance of cholera in the tract of the pilgrims in the Hedjaz. An attempt made to limit cholera to Hamah by a sanitary cordon utterly failed, and was given up; but a like lesson has not been learned from previous experience of the futility of quarantine, and the Levantine ports are now busily employed in pitting themselves against each other as to quarantine restrictions.

A medical commission, consisting of Dr. Millinger, jun., and Dr. Zitterer, has proceeded from Constantinople, under the directions of the Ottoman General Board of Health, to the seat of the outbreak to investigate its origin, and suggest measures for controlling it.

THE VIVISECTION COMMISSION.

The Royal Commission appointed by Government to inquire into the practice of experimenting on living animals has discontinued its sittings for the present, and will not resume them until the 15th of October next. The labours of the Commission up to the present time have been directed to the examination of those persons who, while they hold the highest professional positions, are not supposed to have any extreme views on the subject upon which the Commissioners are engaged. Sir Thomas Watson, a past president of the College of Physicians; Sir George Burrows, the present holder of that honourable office; Sir William Fergusson and Sir James Paget, who stand in similar relationship to the Royal College of Surgeons; Dr. Sharpey, as the representative of British physiologists, and a member of the Senate of the University of London; Mr. Simon, as the guardian of the public health, and the person under whose auspices much experimentation has been carried on; Dr. Acland and Prof. Rolleston from the University of Oxford; Prof. Humphry from Cambridge; Dr. Taylor as the representative of medical jurists and toxicologists, as well as others, have, up to the present time, given the Commissioners the advantage of their valuable experience and opinions. When the sittings of the Commission are resumed in October, those who have laboured chiefly at the scientific branches of the profession, and those also whose duty it is to instruct students in practical physiology, will probably have an opportunity of stating their views. The most eminent of the Scotch professors—Sir Robert Christison, Professor Turner, and Professor Lister—will be invited to give evidence, as well as Professors Burdon-Sanderson and Michael Foster, Dr. Klein, and others. The last batch of evidence taken will be derived from the group of anti-vivisectionists; and these, we hope, will be expected not only to assert, but also to prove their assertions, which some of them have not hitherto shown themselves very ready to do. It will be seen that the labours of the Commission are by no means light, and from the very patient investigation which they seem to be making of the subject before them, there can be little doubt that the report which they will present to Parliament at the commencement of next session will be the basis of some temperate and well-considered regulations which will do for the science of physiology very much what has been effected for anatomists by the Anatomy Act.

INFANTILE SUMMER DIARRHŒA.

The Registrar-General, in his last Weekly Return, calls attention to the fact that, notwithstanding the recent low temperature and abundant rainfall, the fatality from diarrhœa in our large towns continues to increase, and that in London it exceeds the average proportion in the corresponding period of the last ten years. About 80 per cent. of the deaths referred to diarrhœa during July and August are of infants under one year of age, and a very large proportion of the remainder of children aged between one and five years. Diarrhœa is, therefore, as essentially an infantile as it is an urban complaint. Those who know best the unfavourable conditions under which the infants of the working classes are reared in towns feel greater surprise at the number of survivors than at the numbers who fall by the way; but the wide divergence in the death-rate from diarrhœa in different towns affords an important and interesting problem, the effort to solve which only fills one with the conviction how little is yet really known as to the best means for controlling this summer scourge of infant life. The annual death-rate from diarrhœa in the eighteen largest English towns during the week ending the 17th inst. averaged 2·9 per 1000; and whereas not a single death was referred to diarrhœa in Portsmouth, and only one each in Bristol and Sunderland, the death-rate from this disease was equal to 6·7 per 1000 in Leicester, and 7·4 in Nottingham. Year after year this terrible mortality from infantile diarrhœa in Leicester recurs, and no satisfactory explanation of its exceptional fatality in this town has ever been offered. The theory that it is due to the exceptional degeneration of the population of the town is not easy of acceptance, because we do not find that the death-rate in Leicester is abnormally high, except in infancy, and it is difficult to believe that healthy adults give birth to unusually sickly children. The true solution of the problem has yet to be arrived at, and in the meantime it might be useful, as we cannot ascertain why infants die of diarrhœa in Leicester and Nottingham, to inquire why they do not die from this disease in Portsmouth and Bristol.

BLOOD-POISONING FROM SEWER GAS.

The death of Dr. Alexander Crichton, of Mortlake, furnishes another and very sad instance of the effects of sewer gas and of the disasters which are entailed by imperfections in a system of drainage. We have been favoured by Dr. Marshall, of Mortlake, with particulars of Dr. Crichton's illness, which leave no doubt as to its origin. A day or two after his return, in apparently good health, from a visit to Edinburgh, the sewers in his street were opened and cleaned, having been in a filthy condition and very offensive. The process lasted a week, the smell being most unpleasant. The stoppage of a house-drain led to some escape of sewage matter beneath and outside his own surgery. About ten days afterwards he was employed to inspect the ventilation of the sewers, complaints having been made of the odours from the ventilators, some of which he found most offensive. Two days afterwards he complained of headache, followed some days later by vomiting, slight jaundice, and abdominal pain. Delirium followed, and blood appeared in the urine, and subsequently in the vomit. Violent delirium gave place to coma, and slight hæmorrhage from the lungs was added to that from the kidneys and stomach. He died on the eighth day of his illness, an extremely offensive odour having been given off for some hours before death. The temperature, when taken, appears to have been natural, and the bowels were obstinately constipated. The origin of his illness appears clearly to be ascribed to the Mortlake sewers, and this was the opinion of Dr. George Johnson, who saw him before his death. There appears to be a radical defect in the Mortlake drainage, which the remedial measures adopted are quite inefficient to overcome. Our readers will remember the outbreak of low pneumonia in a large school which followed the insertion into a neighbouring drain of one of the ventilators which were, in part at least, concerned in Dr. Crichton's blood-poisoning. We cannot wonder that they are regarded with disfavour by the inhabitants. The free ventilation of sewers into the open air is a necessity, if the air within the houses drained by it is to be kept pure; but the ventilators should be so placed that the inhabitants do not suffer from the means employed for their safety.

DISEASED MEAT PROSECUTIONS IN THE CITY.

In view of the imperative necessity, upon sanitary as well as public grounds, that the enactments provided by the Legislature for the suppression of the traffic in diseased meat should be fairly enforced by the justices before whom such cases are usually tried, we feel it our duty to call the attention of the Governmental authorities to the extraordinary result of a prosecution instituted by the Commissioners of Sewers, as the sanitary authority in the City of London.

We learn from the daily newspapers that on the 2nd inst. four summonses were heard before Sir Thomas White, the sitting Alderman at Guildhall, against persons who were accused of having wilfully transgressed the law by sending meat unfit for human food for sale at the Metropolitan Market, Smithfield.

The first case was that of a man who was charged with having sent the carcass of a diseased cow to London, consigned to a meat salesman in the said market. It was proved by the evidence adduced by the prosecution that the carman who first unpacked the meat at once discovered its unwholesome condition, and that in the opinion of the sanitary inspector who seized the meat "it was in a disgusting and unsound state, and quite unfit for human food." Dr. Sedgwick Saunders, the medical officer of health, was examined, and stated that he had carefully inspected the meat on the day it was sent to London, and found it diseased. He also stated that, in his opinion, the animal had not been slaughtered at all, but had died from disease in a highly "fevered condition" (a term well understood by experts in such matters), and was afterwards "dressed" for market. The Doctor added, with much emphasis, that no person could have eaten such meat without serious danger to health, and that, in his experience, he had never seen a worse case or one more deserving of punishment. Mr. Montagu Williams, who conducted the defence, cross-examined the several witnesses, but without in the smallest degree altering the facts of the case, and then called a Mr. Packman, in whose shop the meat had been seized, and to whom it was consigned for sale. This person stated that, although the meat was not in prime order, "he would not have objected to eat some of it, but would have preferred a piece of Scotch beef," &c., upon which the worthy Alderman said he could not convict in the face of such a statement from a respectable butcher, and that therefore he must dismiss the summons, thereby entirely ignoring the sworn testimony given on behalf of the prosecution, and despite the fact, of which he was informed by the officer of the court, that the defendant *had been previously convicted, and had undergone two months' imprisonment for the same kind of offence.*

Those who know the earnestness with which Dr. Sedgwick Saunders performs his onerous and responsible duties will not be surprised to learn that he was indisposed to submit to this decision. Accordingly we find him alluding to the subject with some force of expression in his weekly report to the Commissioners of Sewers, and complaining of the miscarriage of justice which he alleged had occurred, a complaint which was endorsed by the solicitor who conducted the prosecution, and embodied in that officer's report to the same body.

We have again and again observed with regret the trivial and quite inadequate penalties imposed, notably by the City magistrates, for offences of the description under consideration. The Corporation of London are the market authorities for the greater part of London, and the meat sold within their narrow jurisdiction travels, and is consumed, far beyond their municipal limits. Upon them therefore rests the grave responsibility of affording their fellow-citizens some security against this foul trading.

SWIMMING-BATHS IN THE THAMES.

THE Floating Swimming-baths Company has at length commenced active work, having opened their establishment at Charing-cross to the public during the last fortnight. In general appearance the interior differs but little from those at Lambeth and other parts of London, Vienna, Frankfort, Paris, &c. The general arrangements are very good and comfortable, but, on all grounds, it is a decided mistake to permit smoking. The chief item of interest that concerns us is the state of the water, as the bath derives its supply from the Thames, and it is plain that on this particular point the success of the company very much depends. The process at present adopted is one of simple filtration. The water taken from the Thames is sent through long bags made of stout sea-cotton, the bags being protected by a sort of case or glove. The mud and other suspended particles fall to the bottom of the bags, or are retained in the meshes, the water finds its way into the chamber where the bags are suspended, and is thence pumped into the bath. The bags are of course changed frequently and washed. At certain times of the tide, when water cannot be procured from the river, the bath water is refiltered and sent back again, but when the system is in working order the level of the water is simply maintained by small "overflow" apertures at one end, the inflow and outflow being continuous. The water is in general appearance and colour much like that in the baths in London and elsewhere, but occasionally contains small floating particles, which we have not yet examined microscopically. We may suggest for the consideration of the manager the desirability of sending the water after filtration through a thin layer of charcoal before pumping it into the bath. Such a process would be simple, and, as the charcoal itself can be cleaned at intervals, not costly, and would ensure a much greater amount of actual purity, as well as decolorisation.

ARTIFICIAL RESPIRATION IN APOPLEXY.

IN a recent number of the *Gazzetta d'Italia*, Dr. Corso, the assistant to the chair of Physiology at Florence, advocates the use of artificial respiration in cases of "fulminant" apoplexy, and of compression of the brain by hæmorrhage or other causes. The immediate cause of his remarks was a case related in the same paper, in which a Dr. Despalles of Brussels employed the inhalation of oxygen in a case of apoplexy with hemiplegia with a successful result, the sensibility and power of movement returning in four hours. Dr. Corso claims that artificial respiration was first employed for apoplexy in Prof. Schiff's laboratory, and quotes the opinion expressed by Schiff in his lectures on the nervous system, published in 1866, that in cases of fulminant apoplexy, produced by paralysis of the medulla oblongata, artificial respiration should be used, and never bloodletting. In 1871, Schiff also made numerous experiments on animals, and established the fact that the only way of preserving animals suffering from apoplexy, due to compression of the brain, from certain death, was artificial respiration. The explanation of this fact is that the immediate cause of death is paralysis of the respiratory centres by compression of the medulla oblongata, and the consequent non-oxygenation of the blood. The advantage of artificial respiration over the inhalation of oxygen is that it lowers the pressure of the blood in the intra-cranial vessels, and thus lessens the tendency to further hæmorrhage.

In support of these views Dr. Corso relates a case in which he claims to have employed artificial respiration for the first time in such cases in the human subject. It was that of a lady who fell backwards and sustained a fracture of the skull. When seen, she was cyanotic, insensible, breathing slowly and superficially, the pulse also was infrequent and very feeble, and death seemed imminent. Artificial respiration was immediately performed, and continued for twenty minutes; under its influence the heart's action increased in force and frequency, the respiration became natural, and consciousness returned. The patient did not, however, completely recover, but died fifteen days afterwards from the laceration of the brain caused by the hæmorrhage and fracture. Dr. Corso points out that had it not been for the irreparable lesions produced by the injury, the patient would have lived, and that the artificial respiration gives the brain and the medulla oblongata time to return to their normal functions, and hence a better chance of recovery, at any rate from the immediate danger.

There is no question that in many cases of coma due to compression of the brain, and also in that produced by opium or alcoholic poisoning, artificial respiration might be used with advantage; perhaps also in cases of so-called "congestive" apoplexy; but it seems to us open to grave doubt whether it would be applicable to cases of severe cerebral hæmorrhage. The fear of increasing the hæmorrhage should make us hesitate to adopt it until clearer proof is given that the restored action of the heart would not increase the pressure in the cerebral arteries and destroy that quiescence in which seems to lie the only chance of recovery in many cases. The difficulty in diagnosing the exact cause of the apoplexy will also stand in the way of any general employment of this method, except where it affords the only chance of obviating immediate death.

SCARLET FEVER IN LONDON.

FOR some months past scarlet fever has been unduly prevalent in the various districts of the metropolis, but within the last few weeks it has considerably increased, and must now be characterised as epidemic. We have from time to time alluded in our columns to local outbreaks, such as that occurring in Knightsbridge barracks and in South Kensington. The latter is still the subject of inquiry, and ere long we hope the mysterious circumstances which led to the seizure of so many persons at the same dinner and evening party will be explained. A similar occurrence is reported from West Brompton, when six out of fourteen guests present were attacked. We have received letters from medical men at Brixton, stating that within the last fortnight the number of scarlet fever cases has enormously increased. Similar reports have been received from other districts. Fortunately, hitherto the epidemic, though widely extended, has been of mild character, and the percentage of deaths, to the considerable number of cases, small. An unusual number of adults have been attacked by this epidemic, far more than we remember to have met with before; for though the children, as is usual, form the bulk of the cases, yet the number of adult sufferers is unprecedentedly great. Fortunately the season is nearly at an end, and families will be leaving town, so that, as far as London is concerned, we may hope the worst is over; since it is far easier to secure effectual isolation with the poorer classes than it is with the wealthy, who are often extremely careless and selfish in this respect. What we really fear is the extension of the disease to other districts. At the present time there must be a large number of convalescents preparing to leave their sick rooms for change of air. We can hardly hope that in every case a sufficient interval has been allowed to intervene between the decline of the disease and removal, or that the clothes that may have been in contact with a patient during some period of his sickness have been properly disinfected. If these precautions are neglected, considerable mischief will ensue, and we urge upon the individuals in question the necessity of submitting implicitly to the dictates of their medical attendant on these points. After a slight illness which has only confined the patient to bed for a few days, it seems absurd to him to be confined to his room for a period of three weeks; but he should remember that even in the mildest case the most serious sequelæ of renal complication and dropsy may ensue, and the period of greatest risk from these lies between the sixteenth and twenty-fourth day. His own welfare, as well as that of the public, requires him therefore to bear with patience the confinement and isolation which experience teaches to be necessary for absolute safety.

VENTILATION IN RAILWAY CARRIAGES.

The enormous increase in the gross number of railway travellers in the United Kingdom, the establishment of smoking carriages, and the gradual extension and popularity of saloon cars, all go to direct attention to the ventilation of railway carriages. There can be no doubt whatever that, at the present time, it is deplorably bad, and so we are glad to be enabled to quote some notes upon the subject contained in the last Annual Report of the State Board of Health of Massachusetts. This Board requested Professor Nichols to make some investigations into the character of the air in smoking cars. As a matter of course, it was found that the amount of carbonic acid gas found in the cars greatly exceeds the average in public buildings. A smoking car in America, arranged with tables, chairs, and sofas, will accommodate 50, and an ordinary car 75 passengers. As the average capacity of a passenger car is about 2500 cubic feet of net air space, excluding that occupied by passengers and furniture, 50 cubic feet in the one, and 33⅓ in the other, is given to each occupant. So that, in order to ensure proper ventilation, the air in smoking cars should be changed thoroughly at least every four minutes, and in ordinary cars every three minutes. The report proceeds to explain and criticise the plans adopted on Russian railways by Baron de Dershau for heating railway carriages; but this plan is entirely distinct from any scheme for ventilation, and need not be described here. The main conclusion to which the report above quoted directs attention is, that some system of forced ventilation, or of steam heating and forced ventilation combined, must be found, inasmuch as under the very varying circumstances of travel, comprising number of passengers, rate of speed, amount of smoke, and varying temperature, no natural system can be successful.

It may be contended that no fair parallel can be drawn between the American cars and the carriages on English railroads. But all who have travelled third-class in an "excursion" carriage occupied by at least forty persons must have been conscious of an atmosphere redolent of tobacco smoke, perspiration, and other perfumes, most of which result in carbonic acid, sulphuretted hydrogen, ammonia, &c. It is tolerably evident that saloon carriages will gradually, in England, replace those now in use. And hence, when they are being built, it is well, on the score of health as well as comfort, that some attention should be paid to their ventilation.

KNIGHTSBRIDGE BARRACKS.

A discussion took place in the House of Lords on Monday night with respect to the removal of Knightsbridge Barracks. The military element was strongly represented by the Duke of Cambridge, the Earl of Lucan, and the Earl of Normanton. The Earl of Lucan stated that he had received from the medical officer of his regiment a satisfactory account with regard to the sanitary condition of the barracks and the health of the men. This statement is at variance with that of the Barrack Commissioners, who reported that this building was one of the worst in the kingdom, and, from structural defects, could not be materially improved. The Duke of Cambridge hoped the barracks would be rebuilt and improved, but, from military considerations, he could not advise removal from their present site. We are glad that the defects of the barracks have been admitted by so high an authority, but regret that it will be found necessary to reconstruct them again on the same site, which, in our opinion, is too narrow for the required buildings. Would it not be possible to secure another site in the Park which would give more space? For instance, the ground behind the Royal Humane Society's station on the north bank of the Serpentine seems extremely eligible for such a purpose. It is in the least frequented portion of the Park, it is near the powder magazine, and the open part of the Park on which reviews are held. The removal of the barracks from the neighbourhood of the Knightsbridge-road would improve the value of house property in that district, and as rents rose the "objectionable" tenants would clear off, and handsome mansions appear in the place of the present squalid tenements. Nor do we think that the officers and men would object to such a removal. Spacious, handsome barracks, free from the present disagreeable surroundings, would be far preferable to a reconstruction on the same site of a building that, from want of space, must present many of the objectionable features of the old one.

THE HAMPSTEAD HOSPITAL.

Since our last reference to this subject the Select Committee has held three sittings, and a considerable mass of evidence has been taken. Mr. Shaw Stewart, one of the managers of the Asylums Board and chairman of the Stockwell Hospital, gave evidence in favour of the present site, which he considered not more unsuitable than the Stockwell and Homerton sites. On behalf of the Hampstead Residents' Committee thirteen witnesses have been examined. Mr. Pearson Hill, son of Sir Rowland Hill, read a statement agreed upon by the joint committee of residents and local authorities of Hampstead, stating in detail the grounds of objection to the present site. Dr. Letheby, who was next called, stated that the supposed danger of contamination of the water-supply by the proximity of the proposed site (No. 3) to the reservoir was imaginary, and expressed his belief that that site was in every respect eligible. Dr. Murchison also gave evidence of similar purport. Three of the principal medical practitioners in Hampstead and its neighbourhood, Dr. Cooper Rose, Dr. Anderson, and Mr. Alford, related their experience during the small-pox epidemic, and stated cases in which the contagion was apparently due to the hospital; they also pointed out the dangers which were necessarily involved in the present position of the hospital. Other residents gave evidence as to cases which were apparently traceable to direct contagion from the hospital, and also with respect to the nuisance caused by the ambulance drivers and the use of public conveyances by patients or their friends. Evidence was also given by house-agents of the great depreciation in the value of house property in Hampstead during the epidemic and since the proposition to rebuild the hospital.

The Committee sits again on Friday (to-day), and it is expected that the inquiry will then be concluded.

HÆMATINURIA.

This curious disease was the subject of notice by Dr. J. Warburton Begbie in a recent communication read before the Medico-Chirurgical Society of Edinburgh. One of the two cases related by Dr. Begbie was of considerable interest, both from an etiological and a therapeutic point of view. The patient was a clerk aged twenty-five. The dark colour of the urine appeared first in September, 1873. Up to this time he had always enjoyed good health. No reason is assigned for the appearance of hæmatinuria then. After a few weeks it disappeared, and reappeared in the autumn of 1874, after walking nine miles and being exposed to cold and damp. The urine was never dark before eleven in the morning, doubtless due to the warmth and rest of bed. Before the dark urine was passed there was invariably a sensation of cold and discomfort, but no rigor. The disease resisted gallic acid and large doses of quinine, given to the extent of producing unpleasant symptoms of chinchonism. After the failure of quinine, Dr. Begbie ordered twenty grains of chloride of ammonium, dissolved in water, three times a day. From this day no dark urine was passed. It is true that the weather also became milder. But on two occasions, when the medicine was intermitted, the disease returned. Dr. Begbie regards warmth as the most important remedial agent. Not the least interesting feature of these cases is the evidence they afford of the thermometric delicacy of the renal organs. The value of the chloride of ammonium must be tested by other cases. But its influence here seemed marked, and will justify further use of it in similar cases.

THE PUBLIC HEALTH BILL.

The principal incident in the further consideration of this Bill by the House of Lords was a proposition by Lord Aberdare to strengthen the hands of the Local Government Board in dealing with local authorities. This, he suggested, should be done by enabling the Board, on complaint of its own officer or any other person as to default of duty on the part of the local authority, to step in and supply a remedy. The Duke of Richmond declined to adopt the suggestion, and it fell through. The incident was instructive as showing the extreme crudity of conception of some distinguished members of the House as to the relative functions of the central and the local authorities in local government. Anything more fatal to sound local governmental progress in sanitary matters than investing a Central Board with practically unlimited powers of interference could not well be conceived. Lord Aberdare seems to have yet to learn that there are worse evils than such as arise from defaulting local authorities.

DECLINE OF TYPHUS IN LONDON.

On Saturday, 17th inst., the two Metropolitan Asylum District Fever Hospitals at Homerton and Stockwell did not contain a single typhus patient. Such a fact affords most conclusive evidence of a marked decline in the prevalence of typhus within the metropolis. The fatality of the disease, moreover, has also showed a considerable decrease. The deaths referred to typhus in London during the thirteen weeks ending 3rd inst. were but 46, against 65 and 73 in the corresponding quarters of 1873 and 1874; and in the first fortnight of July only three fatal cases were registered. This decrease of typhus cases and deaths in London is the more satisfactory because the disease showed a somewhat increased prevalence in 1873 and 1874. In 1872 the deaths referred to typhus in London were 175, whereas the fatal cases successively rose to 284 and 312 in 1873 and 1874. The two fever hospitals above mentioned contained on the 17th 31 enteric fever patients, but this number is also unusually small. Owing to the small number of wards of the four fever and small-pox hospitals belonging to the Asylums Board which are now required for the treatment of these diseases, the institutions are to a great extent used for sufferers from scarlet fever, which has recently shown an increasing prevalence, more particularly in South London.

THE BRITISH MEDICAL ASSOCIATION.

As we have before stated, the forty-third annual meeting of this Association will be held at Edinburgh on Tuesday, Wednesday, Thursday, and Friday, August 3rd, 4th, 5th, and 6th. The presidential chair will be occupied by Dr. Copeman, of Norwich, Sir Robert Christison, Bart., being the president elect. The various Sections have been arranged as follows:—Medicine: President, Dr. Quain, F.R.S. Surgery: Professor Lister, F.R.S. Obstetric Medicine: Dr. Matthews Duncan. Public Medicine: Right Hon. Lyon Playfair, M.P. Psychology: Dr. Rowe, F.R.S. Physiology: Professor Burdon-Sanderson, F.R.S. Gentlemen desirous of reading papers, cases, or other communications are requested to forward the titles to the General Secretary, or to one of the secretaries of the Section in which the paper is to be read. No paper must exceed twenty minutes in reading, and no subsequent speech must exceed ten minutes. There will be an exhibition of the latest inventions in medical, surgical, and obstetrical instruments and appliances.

UNVEILING OF PROF. HYRTL'S BUST.

On the 22nd ult. an interesting ceremony took place at Vienna. Our readers are aware that the eminent anatomist Hyrtl resigned his professorship about twelve months ago, and retired into the country accompanied by the best wishes of his colleagues and pupils. Since that time the College of Physicians have resolved to place his bust in the principal hall of the University; and at the above-mentioned date Hyrtl was invited to be present at the ceremony of unveiling. The Prime Minister, Prince Auersperg, and several heads of departments, represented the Government; the University and the Faculty of Medicine had sent numerous delegates, and the students were present in great and enthusiastic numbers. From the description given by the *Allg. Weiner Med. Zeit.*, nothing could surpass the eloquence and warmth displayed in the speeches, and the discourse delivered by Hyrtl himself was expressive of heartfelt gratitude and humility respecting his wonderful and patient labours carried on for forty years in the field of anatomy and experimental physiology. The ceremony was followed by a dinner, during which the most flattering testimony was borne to Hyrtl's worth; and this indefatigable and good man, honoured by his colleagues and numerous pupils, may well be proud in his retirement of the approval of his contemporaries.

THE STORAGE OF WATER.

The copious supply of rain with which we have been favoured during the past fortnight should naturally lead to the calculation as to what proportion of it will be saved and what wasted. Mr. Bailey Denton is continually drawing public attention to the enormous waste of rain-water in England in consequence of the absence of any provisions for storage, and this, too, when a good and continuous water-supply is one of the much-debated problems of the day. It is rather less than a year ago since we drew special attention to this subject (*apropos* of a circular issued by the Local Government Board), and advised rural sanitary authorities to adopt the plan carried out from time immemorial in many other countries, particularly in the East, and build tanks in every chief town and village. Had such tanks existed, a supply might during the past week have been obtained and stored sufficient for the wants of the population during the next eight or ten months.

THE EXAMINATION FOR THE L.R.C.P. LOND.

It will be in the remembrance of our readers that some little sensation was caused at the meeting of the General Medical Council in reference to an adverse criticism made by the visitors of examinations upon the clinical portion of the examination for the qualification of Licentiate of the Royal College of Physicians of London. The matter, as will be noticed from an article in another portion of our columns, came before the College on Monday last, and if the facts stated by Dr. Sibson be true (and there can be no reason to doubt the specific statement he advances), the complaint made by the visitors dwindles considerably in proportion. We shall await the specific answer to the charges which the College has requested its Council to frame; meanwhile we may add that it was a mistake to appoint two *surgeons* to criticise a *medical* examination.

SANITARY MEDICINE AT WALTON-ON-THE-NAZE.

The Commissioners for improving the town of Walton-on-the-Naze do not seem to sufficiently prize the public health of which they are the custodians. They have coolly proposed to reduce the salary of the medical officer of health from £40 to £10! The officer in question, Dr. Grimshaw, feels naturally hurt by such a disparaging suggestion. He has held the office in question for three years, and this with excellent results. Several epidemics have been prevented from spreading, and the state of the public health has been very creditable. Such a state of matters is of great value to a seaside resort. Instead of justifying the lowering of Dr. Grimshaw's, salary, it indicates the propriety of raising it. Surely no local medical man will be a party to the contemplated procedure.

ALL WORK AND NO PAY.

Lord Carnarvon has invited the College of Physicians, indirectly and politely, it is true, but still not the less certainly, to edit and publish, at *its own cost*, the more important portions of the various official papers and reports that are received at the Colonial Office relative to medical questions in the colonies. Lord Carnarvon does not feel disposed to ask the Treasury to find payment for such work as this. We cannot but express our surprise at his lordship's proposal, and do not wonder that the College, as will be gathered from a notice of its meeting on Monday, declined to ask any of its body to do this public colonial work just "for the honour of the thing." Lord Carnarvon must surely be aware that it would be a laborious undertaking, and that unpaid work is seldom, if ever, well done.

SOCIAL SCIENCE CONGRESS.

The arrangements for the ensuing Congress at Brighton are progressing actively. Lord Aberdare is to preside over the meeting generally, and Sir Charles Reed will preside over the Department of Education. The Health Department will be presided over by Dr. Richardson, whose labours both as a sanitary scholar and as a practising physician are thus honourably recognised.

MORTALITY AT SEA.

The annual parliamentary paper showing the mortality among sailors at sea has just appeared. A total of 4602 deaths are recorded, as compared with 5393 in 1873, and 4123 in 1872. The usual classification is adopted, so that, as we have before remarked, no reliable comparison can be made with the mortality in this and any other section of the population. Masters of ships are not included in the list. Sixty deaths are scored up to natural, and 161 to unknown, causes. What are natural causes? Is it not possible to classify such cases under one of the ten groups of diseases that compose the list? And why is it that, except in cases of murder, no inquiry as to so-called accidental deaths at sea ever takes place? The law as it now stands is, on these points, specially defective, and this return is absolutely valueless for showing us either the actual or the comparative mortality that occurs among sailors at sea.

BLUE URINE.

In a case recently described to the Société de Biologie by M. A. Robin, a curious blue tint of urine corresponded to attacks of lumbar pain. The urine was scanty, not actually blue when passed, but on standing a sediment fell in which were many deep-blue granules, distinct under the microscope, showing no trace of crystallisation. The nuclei of cells of bladder epithelium were also stained blue. Urea and uric acid were lessened in amount. The blue substance was a little soluble in water, hardly soluble in alcohol or ether, insoluble in chloroform or alkalies, soluble in sulphuric acid, with a tint at first rose then reddish-orange; soluble in hydrochloric acid, with a magnificent carmine colour. It corresponds closely with the cyanourine of Braconnet, who believed it to be a transformation of uric acid, less oxidised than urea.

At some recent excavations on the Thames Embankment, near the Houses of Parliament, some relics of a very distant age have been discovered. They consist chiefly of bones of extinct quadrupeds and birds, but among them was found the under jaw-bone, retaining all the molar teeth, of a man. There was also found the upper jaw, palate, facial bones, and eye-sockets of an animal of the rodentia order. This fragment is nearly of the same size as the like parts of man, and but for the position of the rodent teeth and the absence of the canine teeth, might be mistaken for a portion of the human head. It is stated, however, that no animal of the rodentia order of so large a size is known to have existed in this country within the period of human history. With these extremely interesting remains was found a flint-knife, fashioned of course by human skill at some remote period. We trust that a careful descriptive account of these fossils will appear in a short time. The "find" is one of transcendent interest to naturalists and comparative anatomists throughout Europe.

In a report of the Chinese Hospital at Shanghai, recently published, we find that the medical officer of the institution, Dr. Johnston, speaks almost rapturously of the value of the subcutaneous injection of atropine in opium-poisoning. During the last ten years upwards of 500 such cases of poisoning (nearly all suicidal) have come under his own observation, 62 having been recorded last year. Many of the most desperate cases rallied and recovered under the treatment advocated. The loss of life annually in China from abuse of the drug must be appalling. Opium-smokers to the number of 360 were treated in the hospital in 1874, but the experience and results obtained were not encouraging, and Dr. Johnston expresses his opinion that it is a hopeless task to reclaim the confirmed opium-smoker.

A meeting was held at the Mansion House on Tuesday, in connexion with the forthcoming exhibition to be held in Brussels next year, to consider the questions of public health and means of preserving life. The meeting was very numerously attended, and an executive committee for London was formed to represent British interests. The congress which will be held in Brussels at the same time will discuss all matters connected with sanitary science, ashore and afloat, as well as the best means to be adopted for saving life from fire and water, for the prevention of accidents in travelling by sea, road, and rail, and for the disposal of the dead. A vast variety of subjects are proposed to be embraced, and if the affair is well organised, good and practical results ought to be obtained in the way of preventing disease, maintaining health, and saving life.

The annual report of the Dublin Fever Hospital and House of Recovery shows that 858 patients were admitted during the past year. The deaths amounted to 90, and represented a higher mortality than usual. This excess was chiefly owing to the large number of cases of scarlatina, enteric fever, and pythogenic pneumonia. Dr. Grimshaw, the physician to the hospital, adduces his reasons for terming the pneumonia "pythogenic." He states that he has traced it distinctly to a miasmatic source, and that it prevails in the spring and summer months. He thinks the disease should now be looked upon as a specific fever, the lung affection bearing the same relation to the fever as sore-throat does to scarlatina, ulceration of the intestines to typhoid, or inflammation of the membranes of the spinal cord to cerebro-spinal fever.

In the annual report of the health of Chester just issued, Mr. Kenyon, the medical officer of health for the town, makes a few observations on the prevalence of puerperal fever in the district last year. A large proportion of the midwifery cases in country towns are conducted by midwives. When puerperal fever appears and certain midwives have to cease practising and to relinquish their engagements, it is not always considered that a woman's only source of income is, perhaps, taken from her, and that she may starve or go into the workhouse. Mr. Kenyon proposes that a sum of money should in some way be made available for supporting a midwife during the period of her suspension. The suggestion is a good one, and it would not be very difficult to put it into practice.

We understand that the Local Government Board will shortly undertake an inquiry into the various processes for the disposal of sewage, and will report thereon. It is said that Mr. Read, M.P., one of the Secretaries of the Board, will be associated with two engineers in the work. It is not very clear what Mr. Read's qualifications for a visitor and reporter of sewage systems are. Would it be unreasonable to hint that the medical profession should be represented in such a commission?

A portrait of the late Rev. Andrew Reed, D.D., the founder of the Earlswood Asylum for Idiots, Redhill, Surrey, was unveiled last week in the presence of a large assembly of ladies and gentlemen. The ceremony seems to have been an important affair, and has been described at length in the daily papers. The late Dr. Reed was a well-known philanthropist, and created several large charities besides the Earlswood Asylum.

Mr. Cross stated last week in the House of Commons that the return relative to the Infant Life Protection Act, 1872, was nearly complete, and would shortly be laid before the House.

Another importation of small-pox into the port of London occurred on the 17th inst. The vessel was visited by the officers of the port authority immediately after hauling into dock, the patient was removed to Stockwell in the nearest ambulance, and the forecastle of the ship as well as the belongings of the crew were fumigated and disinfected.

In London last week 1481 deaths were registered, including 4 from small-pox, 27 from measles, 90 from scarlet fever, 10 from diphtheria, 61 from whooping-cough, 26 from different forms of fever, and 204 from diarrhœa. It will be observed that the fatality from diarrhœa continues to increase.

The International Congress of Ophthalmology will meet in New York in September, 1876. The committee are making great efforts to secure a large attendance, and one that will leave its mark on scientific ophthalmology. They earnestly desire the co-operation of the medical profession in Great Britain.

An official inquiry into the cases of scurvy reported in The Lancet last week has been ordered by the Marine Department of the Board of Trade, as some doubt exists as to the quality of the provisions that were served out to the crew during the homeward passage.

A fever-stricken ship put into Falmouth a few days ago having on board six dead sailors and several who were ill. The master and steward were the only members of the crew able to do anything. The cause of the outbreak has not yet been stated.

Dr. George Buchanan was elected President of the Society of Medical Officers of Health at the annual meeting held on the 16th inst.

Mr. William Soper, M.R.C.S., has been appointed a Manager of the Metropolitan Asylums Board.

ROYAL COLLEGE OF PHYSICIANS.

A meeting of the College was held on Monday last. The Registrar read a further communication from the Colonial Office relative to the publication of the official documents and medical reports received at the Colonial Office from time to time from the colonies. Lord Carnarvon had previously applied to the College for information as to the best way in which this could be done, in the belief that such publication would throw much light upon the geography of disease, and advance the cause of the public health in our dependencies. The College had already stated that the records should be published under the supervision of a physician of acknowledged ability. Lord Carnarvon now replies that he was not prepared to ask the Treasury to find the remuneration for such a duty, and he wished to place the documents at the disposal of the College of Physicians; but the College showed no disposition to take any further steps in the matter.

A second communication from the Colonial Office was read, calling attention to a recent article on Leprosy—especially the observations on the heredity and contagiousness of the disease,—published in the *Medico-Chirurgical Review*, and asking to be informed if there is anything in the facts or statements therein adduced or made which would lead the College to modify the views which it has recently expressed, and in which it asserted the non-contagiousness of leprosy, and as to other points. The old Leprosy Committee, consisting of the senior censor, Dr. Farre, Sir Wm. Gull, Dr. Milroy, Dr. Owen Rees, Dr. Greenhow, Dr. Tilbury Fox, and Dr. Fayrer, were re-appointed to report upon the matter.

A petition from various lecturers on insanity was read, praying that a three months' course of work in the wards of a lunatic asylum might count as part of the compulsory term of clinical study demanded of candidates for degrees. The College was informed that the Censors' Board took a favourable view of the request, and it has been acceded to by the College.

The Registrar then read several communications from the General Medical Council, the only important one being the criticism of the visitors appointed to attend the examination for the licentiate degree. This has been fully referred to before in the report of the General Medical Council. The two chief points in the report had reference to the asserted insufficiency of the clinical examination in the wards, it being conducted on the occasion reported upon by only one examiner, who had nine men to examine in two hours and a half, and that in a hurried way. Dr. Bennett read a report, in which he stated that at the meeting of the General Medical Council he was compelled to admit that the number of examiners on the occasion in question was insufficient. The examiner implicated, Dr. Sibson, in a short statement of facts, called attention to two chief inaccuracies in the report of the visitors. They stated (1) that the examination lasted only two hours and a half, whereas it was three hours and a half, *the visitors having left before the end of the examination;* (2) that at the end of twenty minutes the comments of the candidates were read over, whereas half an hour was the least time given to the candidates for their reports on cases. As to the asserted hurry, Dr. Sibson said this was scarcely consistent with the remark of the visitors that when doubt was experienced on the part of the reporting candidates they were helped somewhat to a proper conclusion, or a new case was given them. And the visitors omitted to state that each student was given two cases to report on, upon each of which he could spend half an hour. Dr. Sibson stated in reference to other points that he spent two hours in the wards the day before the clinical examination over the cases. Both examiners were *hospital surgeons,* and, it is said, spent some part of their visitation time in the surgical wards.

A discussion ensued, in which a strong opinion was expressed as to the satisfactory nature of Dr. Sibson's explanation, though the deficiency in the number of examiners was tacitly allowed to be a real defect. The report of the visitors, Dr. Sibson's explanation, and Dr. Bennett's report were referred to the Council, with instructions to prepare a suitable reply to be forwarded to the General Medical Council.

DR. OTIS AT UNIVERSITY COLLEGE HOSPITAL.

DR. OTIS is an eminent American surgeon, who has gained great reputation in New York by his ingenious inventions bearing upon the treatment of stricture of the urethra. He has peculiar views as to the manner of dealing with this complaint, and had an opportunity, on the 7th inst., by the courtesy of Mr. Berkeley Hill, of operating in the theatre of University College Hospital, before a large assembly of students and medical men, upon a patient affected with stricture. Dr. Otis used the different instruments he has had constructed for the purpose, and being Clinical Professor of Genito-Urinary Diseases at the College of Physicians and Surgeons of New York, is evidently accustomed to lecturing; for he offered, in clear and forcible language, a sketch of his tenets regarding the treatment of urethral stricture, and described, whilst showing them to his hearers, his instruments in such a manner that the principle upon which their construction is based was perfectly understood. A little tinge of humour gave additional attraction to the lecture.

Dr. Otis considers that no reliable standard of the size of the urethral canal can exist; and he generally measures the calibre of every individual urethra by an ingenious instrument which he calls urethrometer. This consists of a straight tube, the end of which can be made to dilate into a kind of fenestrated sphere, the latter corresponding to a dial plate at the handle, which marks the size of the sphere. By this the normal calibre of the urethra can be accurately measured, as also the circumference of the stricture. As to the size of the urethra, Dr. Otis has found, by numerous measurements, that a certain relation exists between the circumference of the flaccid penis and the calibre of the canal. Now when this calibre has been ascertained by means of the urethrometer, a bulbous sound of the corresponding size should be introduced. If it passes easily, this may be accepted as representing the normal calibre. If only a smaller size will enter, the difference between this size and that indicating the normal calibre will show the exact amount of contraction present at a given point.

Dr. Otis showed the urethrometer and his polished steel bulbs fixed on slender shafts, and used them on a young patient brought into the theatre affected with stricture connected with discharge. The lecturer then contended that his system is superior to all others, as, either by gradual dilatation, rupture, internal division, or perineal section, the patients are not cured, because they must, for the remainder of their lives, use dilating instruments, this not being an actual cure. By using his dilating urethrotome, after having mathematically (as described above) ascertained the size of the patient's urethra and the circumference of his stricture, he claims to cure the latter radically. No instrument is afterwards used, save for the first few days, both to arrest hæmorrhage and protect the cut surfaces from the contact of urine. Patients have been seen three and four years after operation, and found quite well. Thus Dr. Otis combines dilatation (not rupture) with division.

The dilating urethrotome consists mainly of a couple of parallel bars, which are separated at will by means of a screw at the handle; the upper bar carries a canula, in which a narrow blade is concealed, which is made salient by being drawn forward, or pushed backwards, over a short elevation on the floor of the canula.

The lecturer, after having ascertained the size of the present patient's urethra and stricture (the dial plates mark the French scale), introduced his dilating urethrotome, opened it to the required extent, and cut the stricture in withdrawing the instrument. The patient seemed to suffer rather sharp pain, and had some hæmorrhage. As the bulbous sound of the corresponding number could not, after this section, be passed, the patient was cut again, and the sound passed readily. Dr. Otis now applied, to cool the organs, a neatly contrived "cold water coil" of indiarubber, on the syphon principle, to demonstrate the manner in which he moderates hæmorrhage.

Another patient was then brought in, but as the actual cutting would have been inconvenient to the young man just at that time, no actual operation took place, and the audience separated highly gratified at the skill of the surgeon, and the fluent delivery of the lecturer.

It remains to be seen how far Dr. Otis's system will shake the other methods now in use among surgeons; but there is no doubt that this dilating urethrotomy deserves the most careful attention, especially as the author of it quotes, in a pamphlet published by Putnam, of New York, in 1875, 100 cases of stricture thus treated, where permanent cures have mostly been obtained. As Dr. Otis promises excellent results without the necessity of bougies for years, and as his instruments are not only ingenious, but pretty easily managed, it is likely that many surgeons will be disposed to give them a trial.

MR. PRESCOTT HEWETT.

A CROWDED and influential meeting was held in the Board-room of St. George's Hospital, on Saturday, July 17th, "to consider the propriety of presenting a memorial to Mr. Prescott Hewett, on his resignation of the office of surgeon to St. George's Hospital, in recognition of his services in the advancement of medical science, and of the influence his character has had on the profession and the public." Resolutions were unanimously and enthusiastically passed approving of the objects of the meeting, and a committee was appointed to carry the same into effect. Sir

James Paget attended by special invitation, and a parallel having been drawn between the career of Sir James Paget and Mr. Hewett, Sir James said that scarcely anything had happened to one that had not in a few months after happened to the other. He might next year be president of the College of Surgeons, and the year after it would come to Mr. Hewett's turn. Sir James said he could follow the similarity in many more details, but refrained from doing so lest it should appear that he in any degree, in character, resembled one who had been for many years his great rival in friendship as in other things.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

THE thirteenth annual meeting of this Society was held in the Council Chamber on the 13th inst. The yearly report submitted by the secretary showed that the Society had made a great advance during its past session. The members had increased from forty to fifty, and their attendance at the ten meetings of the session had been nearly one-half greater than that of previous years. The communications submitted to the meetings, of which upwards of thirty had been made, had shown more general research and originality than previously. One evening of the session had been devoted to a general discussion upon the subject of vaccination, its benefits and dangers. The result determined the Society to repeat such discussions upon some debated medical subject, every succeeding session. A number of important morbid specimens had been added to the pathological department. The Society in all respects, financially and otherwise, was pronounced to be in a most prosperous condition. The following gentlemen were elected as office-bearers for the ensuing session:—President, E. Bronner; Treasurer, W. Whalley; Secretary, D. Goyder; Committee, R. H. Meade, J. Foster, P. E. Miall, and J. Dunlop; Pathologists, M. Lee and A. Rabagliati; Auditors, W. H. G. Buckley and C. H. Taylor.

Correspondence.

"Audi alteram partem."

QUACK MEDICINES.

To the Editor of THE LANCET.

SIR,—With your permission I should like to draw your attention and that of your readers to a subject which, I think, is of considerable importance to the medical profession. Every medical man knows that there is a handful of men who have stepped out of their own legitimate and respectable calling, and who deal extensively in quack medicines and secret nostrums, often of their own making, and who call themselves consulting and operating chemists. The advertisements of these men penetrate every house, for you cannot take up a periodical or newspaper that is not full of them. I have a local paper before me which contains twenty-five of these advertisements, one person having inserted fourteen. When reading these advertisements one is at a loss to know at which to be most astonished—the assurance of the writers of them or the credulity of those who read them. Dr. Fergusson, of Bolton, said the other day in his report before the Royal Commission sitting in Manchester, that the populations of large towns were degenerating, and the chief causes to which he attributed this state of things were drunkenness and smoking. I think he might also have added the drugging of children and the consumption of quack medicines to which the working classes are, with a strange infatuation, addicted; this propensity caused no doubt by the insinuating advertisements, and, for the most part, made up testimonials which are constantly kept before the public. Can nothing be done to stop all this? But until something is effected by legislation, if THE LANCET would devote some of its valuable space to the analysis of some of the principal quack medicines, great good would be done to the medical profession and to the public. Dr. A. S. Taylor, M.D., F.R.S., Lecturer on Medical Jurisprudence, &c., in Guy's Hospital, has kindly just analysed a noted medicine called "Clarke's Blood Mixture," and has appended to his report some valuable remarks and suggestions. It will be seen from the analysis that the active principle of this mixture is iodide of potassium in four-grain doses for an adult, four times a day. I need not tell my professional brethren the injurious effects the prolonged use of this drug must have on the weak and anæmic, who are the people mostly likely to take this mixture attracted by its name. It is probable that many medical gentlemen, especially those in large towns, have treated patients suffering from the effects of quack medicines. If in future they will kindly take notes of such cases, and from time to time insert them in the medical journals, they will confer a great boon on the profession and a greater boon still upon the public at large.

I am, Sir, your obedient servant,

Lincoln, July 19th, 1875. WILLIAM O'NEILL, M.D.

[COPY.]

Report of Analysis of a Liquid described as "Clarke's World-famed Blood Mixture or Purifier."

A bottle containing this mixture was forwarded to me by Dr. W. O'Neill, of Silver-street, Lincoln, with a request that I would make an analysis of it, and inform him of its composition.

The bottle was enclosed in several paper-wrappers, setting forth a number of cases in which it was alleged that this "blood mixture" had wrought many cures in a variety of diseases.

The quantity of liquid contained in the bottle was eight ounces. It had a dark brown colour, but was clear and free from any sediment. It had the smell of chloric ether (a compound of chloroform and alcohol), and a sweetish saline taste which was not unpleasant. Its reaction on test paper was alkaline. On shaking it, it formed a brown-coloured froth. When evaporated to dryness, it left a thick dark saccharine extract, weighing for the half-ounce about twenty-nine grains. When this extract was incinerated, it left a white saline residue which proved to be *iodide of potassium*. The brown colouring matter had the usual properties of burnt *sugar* (caramel), the colouring which is used to give a brownish tint to brandy, sherry, and other pale wines. In addition, the mixture contained a small quantity of a solution of potash, just sufficient to correct the acidity of the burnt sugar. Alcohol and chloroform (as chloric ether) were detected in it. Arsenic, antimony, lead, copper, and other metallic poisons were sought for, but the mixture was found to be quite free from any metallic impregnation.

The composition of the mixture was found to be as follows in eight ounces:—Iodide of potassium, 64 grains; chloric ether (B.P.), 4 drachms; solution of potash (liq. potassæ B P.), 30 minims; water coloured with burnt sugar to the requisite tint, 7½ ounces.

There was no injurious ingredient in the mixture. The chloric ether is a pleasant stimulant, but the *iodide of potassium* is the efficient medicinal agent. The dose of this salt is moderate; it amounts to about four grains in each tablespoonful, but this dose is directed to be taken by adult males four times a day, making a daily quantity of *sixteen grains* of the iodide of potassium.

Why such a mixture as this should be designated a "blood mixture" and a "blood purifier" is incomprehensible. It has no more claim to these titles than nitre, common salt, sal ammoniac, or other saline medicines which operate on and through the blood by absorption. The iodide of potassium has been long used by regular medical practitioners in the treatment of scrofulous, syphilitic, and rheumatic diseases. Its properties are well known, and there is no novelty in its employment. The only novelty in this form of mixture is that the iodide is dissolved in water coloured with burnt sugar, and it is described as a "blood purifier."

Iodide of potassium, when used in proper doses and employed in cases which really require it, is a good, safe, and useful medicine. Although in each tablespoonful of the mixture the proportion of iodide is small, yet the four doses directed to be taken daily represent *sixteen grains*, and if the person taking it is not under medical observation, such a daily quantity as this may accumulate in the system and do mischief.

In some constitutions the iodide of potassium frequently taken, even in medicinal doses, proves speedily injurious. It produces a diseased condition, to which the name of "iodism" has been given. In one instance, three grains, taken three times a day, caused, after the fourth dose (twelve grains), shivering, headache, thirst, quick and full pulse, with vomiting and purging. In another case a dose of five grains caused difficulty of breathing, discharge from the eyes and nostrils, inflamed conjunctiva, and most of the symptoms of a severe cold, for which these injurious effects of the iodide may be easily mistaken. In some cases the iodide has acted powerfully on the salivary organs, causing salivation. In others it has acted powerfully on the kidneys, and has produced a copious flow of urine. These facts show that it is not a medicine which can be safely taken in quantities of sixteen grains daily by a person who is not under medical observation.

The sale of medicines of this kind should be strictly prohibited, unless the bottles containing them were supplied with a caution label setting forth their true composition. It is only reasonable that a person should know what he is purchasing; but the rule of English law applied to such cases is the same as in the buying of a horse, *Caveat emptor.* A man who has reached adult age is supposed to be able to exercise a sound judgment for himself, although it is notorious that there is no instance in which so much credulity is shown as in the purchase of medicines to which some great curative powers are attributed.

Alfred Swaine Taylor, M.D., F.R.S.,
Lecturer on Medical Jurisprudence and
Toxicology in Guy's Hospital.

St. James's-terrace, Regent's-park,
July 15th, 1875.

ON THE PHYSICAL CAUSE OF THE PRESYSTOLIC MURMUR.

To the Editor of The Lancet.

Sir,—I should deem it almost impossible for anyone with an unbiased mind, a correct ear, and an adequate experience to have failed repeatedly to verify the accuracy of Dr. Gairdner's description of the presystolic murmur had we not a few such distinguished instances to the contrary. It is true that this murmur is a difficult one to demonstrate for the first time to many, even of those who can distinguish most of the morbid heart sounds readily. The exceeding sharpness and rapidity with which the first sound succeeds the murmur leads many to regard the murmur as systolic, and to mistake the first for the second sound of the heart. In other cases, again, I have known the murmur to be mistaken for a diastolic bruit. But having once mastered a case, the murmur is a very easy one to recognise when not complicated by the presence of others. The term auricular systolic, used by Dr. Gairdner, is not, however, I venture to think, quite a happy one, inasmuch as it does not describe the whole mechanism of the murmur. It is true that in most cases a bruit is only audible with the accelerated passage of blood through the narrowed mitral orifice during auricular systole. But both thrill and murmur may commence before the time of the auricular systole, "extending from the second sound through the pause." Dr. Gairdner speaks of this as an associated murmur, the noise of the blood stream attracted towards the expanding ventricle. It is, however, as far as I know, peculiar to cases of mitral stenosis, being prolonged and intensified up to the systole by the contraction of the auricle. The current of blood propelled during the pause by the residual force of the ventricular contraction may, as I think Dr. Salter has pointed out, in certain cases of mitral constriction (especially in the funnel-shaped mitral) be sufficient to set the valve vibrating, and to give rise to a continual *bruit* extending from the second sound through the pause to the first, and being augmented by the increased tension of blood when the auricle contracts. Since, then, narrowing of the mitral orifice is the only condition necessarily present at all periods of the murmur, I think the older terms mitral-constrictive or presystolic preferable to that proposed by Dr. Gairdner.

I am, Sir, yours faithfully,
R. Douglas Powell, M.D., F.R.C.P.,
Physician to the Hospital for Consumption and Diseases of the Chest at Brompton.

July 19th, 1875.

"PASS" AND "PLUCK" AT THE COLLEGE OF SURGEONS.

To the Editor of The Lancet.

Sir,—I think it would have been fairer to the various medical schools if the report of the examiners, which was published last week, had been supplemented by another set of statistics, showing the number of registered students at each school who have completed the studies required for the primary and pass examinations respectively.

I have had the curiosity to place in parallel columns—(1) the number of students at the various metropolitan schools who registered for the first time in October, 1873, and who therefore should have been candidates at the primary examinations in April and May last; and (2) the number from each school actually examined during the whole year:—

	No. of First-year Students registered in October, 1873.	No. of candidates at Primary Examination in in 1874-75.
St. Bartholomew's ...	100 ...	80·83
Guy's	94 ...	78
University College ...	66 ...	87
St. Thomas's	53 ...	64·3
King's College	46 ...	47
Middlesex	37 ...	26·5
St. George's	34 ...	31·5
London	38 ...	41
St. Mary's	21 ...	25·5
Charing-cross	13 ...	13·5
Westminster	12 ...	10

It is obvious from this list that the residuum of students who have been kept back from the primary examinations is much greater at some schools than at others, and this consideration materially modifies any estimate that is made of the relative merits of the teaching of anatomy and physiology.

I remain, Sir, yours very faithfully,
July 20th, 1875. A Teacher.

CONTAGION OF PUERPERAL PYÆMIA.

To the Editor of The Lancet.

Sir,—I observe in your issue of this day (July 17th) that my friend Dr. Fordyce Barker represents me as holding that what is called "puerperal fever" is not contagious. You will give me space to correct this error of his. I not only have never said that it is not contagious, but I have said it is "communicable," or, in ordinary language, contagious. I am, Sir, your obedient servant,

Edinburgh, July 17th, 1875. J. Matthews Duncan.

A FRAUD PREVENTED.

To the Editor of The Lancet.

Sir,—In one of your recent numbers there is an advertisement asking for a gentleman who has recently passed the L.R.C.P. Exam. of London, to prepare a gentleman for the two examinations for that qualification, and offering a fee of £50. I answered this advertisement, and have to-day received a reply to my letter. To save your space, I may say that the first part of this letter states where the writer of it was educated, and expresses a fear lest he should be unable to pass the examinations by September, when he has to go abroad. Then follows the pith of the letter, which I give in full and *verbatim*:—

"Now, Sir, a few words in strictest *confidence*. If you will present yourself and pass the first and second Royal College of Physicians Examination of Edinburgh (where I am unknown), I will give you the sum of £50, exclusive of traveling (*sic*) and boarding expenses for three days, while the examination lasts. Will meet you at * * * *, and accompany you to Edinburgh, and pay the £50 in any way you mention. Exam. on the 28th of this month, or special."

Nothing but an urgent sense of duty would lead me to publish a letter sent to me in "strict confidence," but secrecy in this case would be participation in a fraud. I cannot conceive that any good can arise from publishing this gentleman's name. I have sent a copy of his letter to the College of Physicians of Edinburgh, and will forward the name to any of the examining boards of the United Kingdom who apply to me for it.

I am, Sir, your obedient servant,

Gower-street, Bedford-square, W.C. A. Pearce Gould, B.S.

PARIS.

(From our own Correspondent.)

The death of Demarquay has been the chief medical topic of the last week, and very many anecdotes touching this eminent surgeon have been related in conversation or published in the journals. Some of his bequests have already been made known. Thus he leaves 100,000 francs to the Academy of Medicine, to be employed either in helping that learned body to select a more suitable place of residence, or in founding an annual prize. In like manner 10,000 francs have been left to the Société de Chirurgie, for founding a triennial prize. His library, which was exceedingly extensive and complete, has been bequeathed to the Maison Municipale for the use of the medical men and students attached to the hospital. His former pupils have inherited his surgical instruments. Besides these scientific and professional bequests, there are others which denote the humanity and religious disposition of Demarquay. Thus certain sums of money have been left to ameliorate the condition of the curate, the sister of mercy, and the village teacher of Longueval, Demarquay's birthplace; 15,000 francs to the poor; 10,000 francs for the charitable institutions of Longueval, &c. It is said that Demarquay's brother inherits all the rest of his fortune, consisting of 800,000 francs, and his fine property of Longueval. But perhaps there is some exaggeration in this estimate of Demarquay's fortune, though he was said, especially during the latter years of his life, to make a yearly income of £6000 by his practice.

In connexion with the floods which have produced such destruction in the south, and spread a general feeling of consternation throughout this country, it is well to mention the proofs of humanity and generosity which have been given by the profession. Besides the invaluable services rendered by the medical men of Toulouse and the other localities to the victims of the floods, the presence of mind and noble behaviour of two internes (house-surgeons) of the Hôtel Dieu of Toulouse deserve to be especially noticed, they having been the means of saving the lives of the inmates of the hospital, more than 200 in number. On June 23rd, at 5 P.M., the waters of the Garonne had invaded the Faubourg Saint Cyprien, and had filled the cellars, kitchens, and pharmacy of the Hôtel Dieu. The whole hospital was disorganised. The servants and patients were helpless from terror. The flood was still rising. The only bridge left, the one opposite the Hôtel Dieu, was threatened with destruction. The general in command had ordered his troops to retire. The wards of the hospital were beginning to be reached by the water, the building began to crack and shake, and every means of communication with the town was cut off. Under these most trying and extraordinary circumstances, MM. Bonneau and Labat, the house-surgeons, took a rapid determination, and, assuming all the responsibility, they decided that the hospital should be evacuated by any means. Owing to their energetic exertions, the 200 patients were conducted or carried safely out of the hospital and over the bridge, amidst the greatest anxiety and the most painful incidents. Two days after, when Marshal Macmahon visited the flooded city, the Prefect presented the two gallant house-surgeons to him, and in the name of the city demanded for them the Cross of the Legion of Honour as a reward for their intrepidity.

The *concours* for appointing two vice-professors of surgery and one of accouchement at the School of Medicine is very nearly ended, the candidates now going through the last test, that of publishing, and arguing on, various theses appointed by the judges. It may be of interest to give a list of the subjects chosen by the Paris professors:—1. The influence of constitutional maladies on the course of traumatic lesions. 2. On arthropathies of nervous origin. 3. On the accidents which may complicate traumatic dislocations. 4. Comparative study of the various methods of exercise. 5. On the value of hysterotomy in the treatment of fibrous tumours of the uterus. 6. On the part played by muscular action in traumatic luxations. 7. Pathogeny, course, and termination of tetanus. 8. On transfusion of blood. 9. Point out the influence which histology has exercised on the progress in diagnosis of tumours. 10. Traumatic lesions of the liver. 11. On the various dispositions of the funis, except procidentia, which can disturb the regular course of pregnancy and parturition. 12. Make known the counter indications of version in presentation of the shoulder, and the means which can be used to supersede this manœuvre. 13. In what cases is it necessary and advisable to procure abortion. All these various theses, after having been printed, will be put in the hands of the various candidates, each one of them having to defend his thesis against two adversaries.

Paris, July 13th, 1875.

Medical News.

Royal College of Physicians of London.—The following gentlemen were admitted Licentiates on the 19th inst.:—

Anningson, Thirkell, Burnley.
Baly, William, St. Mark's Hospital, City-road.
Blackmore, George Henry, Shaftesbury-road, Hammersmith.
Childs, Christopher, Warwick-street.
Clarke, Arthur, Brill, Buckinghamshire.
Clayton, Joseph Everett, Rutland-street.
Collins, Charles Edward, Crowndale-road.
Cooper, Ernest Frederic, St. Paul's-road.
Haines, Edmund William, Tavistock-place.
Hood, Francis Edward Charles, Guy's Hospital.
Irving, Charles, St. Bartholomew's Hospital.
Jackson, Ernest Carr, Harley-street.
Kebbell, William, Brighton.
Kempe, John Arthur, Wimpole-street.
Murrell, William, York-street, St. James's-square.
Pasley, Nicholas Claude Burgoyne, Palace-road.
Peck, Awdry, Yalding, Kent.
Peevor, George Hamilton, Portsdown-road.
Phillips, Arthur Owen Henry, Bethlem Hospital.
Poynder, George Frederick, Weeting, Brandon.
Ree, Frederick George, Ealing.
Reid, Thomas Whitehead, St. Bartholomew's Hospital.
Rendall, John, Maiden Newton, Dorchester.
Robson, Arthur William Mayo, Leeds.
Romano, Frederick William Richard, Albany-road.
Rudd, Leonard, Guy's Hospital.
Spooner, Frederick Henry, Plymouth.
Thompson, Alfred, Spilsby.
Waylen, George Swithin Adee, Granville-square.
Williamson, Francis, Durham-place.

Royal College of Surgeons of England.—The following gentlemen, having passed the required examinations for the diploma, were duly admitted Members of the College at meetings of the Court of Examiners on Tuesday and Wednesday last:—

Alford, George E., Weston-super-Mare.
Blake, Andrew Henry, L.S.A., Castle-street East.
Briggs, William H., Stroud, Gloucestershire.
Chippingdale, Samuel Dodd, Commercial-road.
Clayton, Joseph Everett, L.R.C.P. Lond., Leeds.
Clinton, Samuel A., M.D., L.S.A., Chislehurst, Kent.
Crouch, Ernest I., L.S.A., Hornton-street, Kensington.
Daubeny, Charles A., Yatton, Somerset.
Eames, James Crompton, M.B. Edin., Manchester.
Gawith, James Jackson, L.S.A., London.
Haines, Edmund W., L.R.C.P. Lond., Tavistock-place.
Hayward, William T., L.K.Q C.P. Irel., Liverpool.
Hobson, Lewis John, Ainger-terrace.
Hood, Francis E. C., L.R.C.P. Lond., Bletchingley, Surrey.
Hunter, Robert H. A., Dalston.
Irvine, Delaware Lewis, Newcastle.
Jones, Thomas R., L.R.C.P. Lond., Walton, Lancashire.
Jumeaux, Benjamin, L.R.C.P. Edin., Stafford.
Latour, George Lewis, Lambeth.
Lumby, John R. H., Birmingham.
Mitchell, Charles J. C., L.S.A., Bedford.
M'Naught, James, M.B. Edin., Wall, Northumberland.
Ormerod, Joseph Arderne, Oxford.
Palmer, Francis C., Weston-super-Mare.
Peevor, George Hamilton, L.R.C.P. Lond., Portsdown-road.
Richards, Thomas, Cardiff.
Skipworth, Herbert, Brigg, Lincolnshire.
Smith, Charles Callow, L.S.A., Redditch.
Sparrow, George Gordon, L.R.C.P. Edin., Southsea.
Street, Alfred W. F., Barnetby, Lincolnshire.
Sykes, William, L.R.C.P. Edin., Sheffield.
Symonds, Charters J., St. John's, New Brunswick, Canada.

Thomas, Edmund F., L.R.C.P. Edin., Weston-super-Mare.
Tindle, John G., Middlesborough.
Vernon, William, L.R.C.P. Edin., Newcastle-on-Tyne.
Watkins, Arnold H., M.B. Edin., Nailsworth.
Wilson, Arthur C. J., Manchester.
Winship, William L., Newcastle.
Wright, Newton W., Ardwick, near Manchester.

The following gentlemen passed the Primary Examination in Anatomy and Physiology on the 15th inst.:—

Messrs. A. P. Cooper, E. Denning, E. C. Bentham, H. D. Cooper, W. T. Atkey, and R. R. Norton, University College; B. B. Fox, E. M. Wilson, and C. W. C. Fletcher, St. George's Hospital; F. W. W. Goodsall, St. Bartholomew's Hospital; H. S. Michell, F. Willcocks, and A. Shipton, King's College; D. E. Thomas and R. H. Grimbly, St. Thomas's Hospital; John Gabe and R. G. White, London Hospital; F. F. I. Blaker, Guy's Hospital; R. C. Revell and E. Semple, Middlesex Hospital; W. Foster, Westminster Hospital; William Scott, Glasgow; and C. H. Hough, Cambridge.

Of the 163 candidates examined during last week, 83 failed to satisfy the Court of Examiners, and were referred for three months' further anatomical and physiological study.

Apothecaries' Hall. — The following gentlemen passed their examination in the Science and Practice of Medicine and received certificates to practise on July 15th:—

Chadwick, Alfred, Heywood, near Manchester.
Crowdy, Frederic Hamilton, Newfoundland.
Fell, Thomas Kennedy, Ulverstone, Lancashire.
Fussell, Ernest, Sherborne, Dorset.
Lilley, George Herbert, Ware, Herts.
Smith, Charles Callow, York-road, Lambeth.

The following gentlemen passed the Primary Professional Examination on the same day:—

Edmund John Thompson, Frank Samuel Goulder, and John Henry Osborne, University College; Thomas William Richardson and John Weller, London Hospital; Frederick De Caux, King's College; Alex. Stuart Brown, St. Mary's Hospital; Thomas Seagrave Sutton, Middlesex Hospital.

In Belfast, for the past quarter ending July 3rd, there were 88 deaths from scarlatina, 10 from small-pox, and 114 from measles. This is an excessively large mortality in a population of 182,000.

Bequests, &c., to Medical Charities.— Mr. Anthony Strutt bequeathed £1000 to the Derbyshire Infirmary. Mr. Edward Lewis, of Chorlton-cum-Hardy, bequeathed £200 to the Manchester Royal Infirmary.

Vaccination Grants.—The Local Government Board has awarded grants to the public vaccinators of the St. Saviour's Union in the following proportion:—To Mr. W. Babbage, £64 6*s.*; Mr. Wright, £50 13*s.*; Mr. Llewellyn, £34 3*s.*; and to Mr. A. Matcham, who has been but recently appointed, £10 3*s.*

Adulteration of Food Act in Sunderland.— Dr. Yeld, public analyst for Sunderland, reports that during the quarter ending the 30th of June last, thirty articles of food and drink were submitted to him for analysis—namely, eighteen samples of milk, seven of bitter and mild ales, three of coloured sweetmeats, one of condensed milk, and one of water. Of the eighteen samples of milk, it was found necessary to prosecute in only one instance, in which 18 per cent. of water had been added, for selling which as pure milk the seller was fined 10*s.* and costs. The coloured sweetmeats were found not to have been coloured with any poisonous ingredient. The sample of water, obtained from a well in Bishopwearmouth cemetery, and which had occasionally been drunk by persons visiting the cemetery, was found to be charged with a considerable amount of organic matter, and quite unfit for drinking.

Health of Dublin.—From the Report of the Registrar-General for Ireland for the June quarter, it appears that the births registered amounted to 2194, and the deaths to 1906, or 24 in every 1000 of the population. The deaths from zymotic affections amounted to 251, being 72 less than in the previous quarter, principally owing to the decline in the mortality from scarlatina; whilst only 2 deaths arose from small-pox, and 6 from measles. The principal causes of death were as follows:—Phthisis 261, bronchitis 253, convulsions 111, heart disease 109, pneumonia 79, hydrocephalus 53, fever 51, scarlatina 42, paralysis 41, apoplexy 39, cancer 37, mesenteric disease 34, diarrhœa 26, croup 20; whilst 49 deaths were accidental, 2 homicidal, and 1 suicidal. The mean of the mean weekly temperature for the quarter was 52·8°; and the rainfall during the thirteen weeks measured 5·058 inches.

In last week's return, the registrar of Sligo district states that one of the deaths registered during the week was of a person aged 106 years.

Medical Appointments.

Anderson, Prof. A. G., has been appointed Public Analyst for the Parish of Paddington, vice Hardwicke, resigned: £150 per annum.

Bothwell, G. G., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer for the whole of the Leighton Buzzard Union, vice Harris and Etheridge, resigned; also Medical Officer of Health for the Leighton Buzzard Rural Sanitary District.

Brickwell, B. A., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Amersham District and the Workhouse of the Amersham Union, vice Courtney, resigned.

Cartwright, A., M.R.C.S.E., has been appointed Surgeon-Dentist to the Hospital for Sick Children, Great Ormond-street, vice Edgelow, resigned.

Clarke, J., L.R.C.S.I., has been appointed Assistant-Surgeon and Registrar to the County Down Infirmary, Downpatrick, vice Lawder.

Craigmile, A., M.B., C.M., has been appointed House-Physician to the Northern Hospital, Liverpool, vice Barr, resigned.

Crawford, S. K., M.D., L.R.C.S.Ed., L.M., has been reappointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Tandragee Dispensary District of the Banbridge Union, Co. Armagh.

Davies, H. H., M.R.C.S.E., has been appointed Medical Officer for the Llandyssul District of the Newcastle-Emlyn Union, vice Jones, deceased.

Davison, F. V., M.B., C.M., has been appointed House-Surgeon to the Bootle Borough Hospital, vice Knox, resigned.

Edmond, W. R., L.R.C.P.Ed., M.R.C.S.E., has been appointed Assistant Resident Medical Officer to the Swansea Hospital, vice Collins, appointed Resident Medical Officer.

Farnell, H. D., M.R.C.S.E., has been appointed House-Surgeon to the Northern Hospital, Liverpool, vice Harris, resigned.

Harries, J. D., M.R.C.S.E., has been appointed Medical Officer to the Salopian Hope Lodge of Odd Fellows, Shrewsbury.

Hawkes, A. M., M.R.C.S.E., has been appointed Medical Officer for the No. 1 District of the Launceston Union, vice Sargent.

Hepburn, D., L.D.S. R.C.S.E., has been appointed Assistant Dental-Surgeon to the Dental Hospital of London, vice Tomes, resigned.

Holderness, W. B., M.R.C.S.E., has been appointed Medical Officer of Health for the Huntingdon Urban Sanitary District: £24 per annum.

Jones, J. T., L.K.Q C.P.I., L.M., M.R.C.S.E., has been appointed a Medical Officer to the Brixton, Streatham, and Herne-hill Dispensary, vice Mercer, deceased.

Leftwich, R. W., M.B., C.M., M.R.C.S.E., has been appointed Resident Medical Officer to the East London Hospital for Children and Dispensary for Women, vice Stocker, resigned.

Lloyd, A. E., L.R.C.P.Ed., L.M., M.R.C.S.E., has been appointed Medical Officer of Health for the Rhyl Urban Sanitary District, vice Williams, resigned.

Lodge, J., M.R.C.S.E., has been appointed Medical Officer for the Keynsham District of the Keynsham Union, vice Moir, resigned.

Mackinlay, J. E. H., L.R.C.P.L., M.R.C.S.E., has been appointed a Medical Officer to the Coatham Convalescent Home, vice Oliver, resigned.

Marsh, W. A., M.R.C.S.E., has been appointed Medical Officer to the Salop Medical Aid Association, Shrewsbury, vice W. J. Marsh, M.R.C.S.E., resigned.

Marsh, W. J., M.R.C.S.E., has been appointed Medical Officer to the William Watkins Lodge of Odd Fellows, Shrewsbury, vice Willett, deceased.

Mead, H. T. Harvey, M.R.C.S.E., has been appointed Medical Officer of Health for the Christchurch Sanitary District.

Pechey, Miss M. E., has been appointed House-Surgeon to the Birmingham and Midland Hospital for Women.

Philpot, J. H., M.B., Medical Tutor in King's College, has been appointed Sub-dean of the Medical School.

Powell, J., M.R.C.S.E., has been appointed Medical Officer of Health for the Penbryn Sub-district of the Newcastle-in-Emlyn Rural Sanitary District, vice Evans, deceased.

Rendle, R., F.R.C.S.E., has been appointed Resident Medical Officer to the Hospital for Consumption and Diseases of the Chest, Brompton, vice V. Edwards, M.R.C.S.E., retired, after nearly twenty-five years' service.

Thompson, H., M.R.C.S.E., has been appointed Assistant House-Surgeon to the Northern Hospital, Liverpool.

Troutbeck, J., M.B., L.R.C.S.Ed., L.M., has been appointed Medical Officer for the Stanmore District of the Hendon Union, vice Irving, resigned.

Wheatcroft, S. H., L.R.C.P.Ed., M.R.C.S.E, has been appointed Medical Officer for the Oxborough District of the Swaffham Union, Norfolk.

White, Dr. R., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Kilshannig Dispensary District of the Mallow Union, Co. Cork, vice Roche, resigned.

Wilson, J. M., M.B., C.M., has been reappointed Medical Officer of Health for the North Witchford Rural Sanitary District, at the reduced salary of £40 per annum, Chatteris having been severed from it and formed into an Urban Sanitary District.

Births, Marriages, and Deaths.

BIRTHS.

Dove.—On the 15th inst., at Pinner, the wife of J. R. B. Dove, M.B., of a daughter.

Fear.—On the 16th inst., at Brenchley, Kent, the wife of William Fear, M.R.C.S.E., of a daughter.

Gardner.—On the 9th ult., at Naini Tal, India, the wife of T. T. Gardner, M.R.G.S.E., Surgeon-Major Army, of a daughter.

Heron.—On the 13th inst., at King's Cliffe, Northamptonshire, the wife of G. A. Heron, M.D., of a daughter.

Pearson.—On the 18th inst., at Upper Phillimore-place, Kensington, the wife of David R. Pearson, M.D., of a son.

Richardson.—On the 10th inst., at Bennington House, Beal, Northumberland, the wife of Henry Richardson, M.D., R.N., of a son.

MARRIAGES.

Beckett—Allden.—On the 20th inst., at St. Michael's Church, Chittisham, Francis Mears Beckett, M.R.C.S., of Ely, to Harriet Elizabeth, fifth daughter of the late Wm. S. Allden, Esq., and Lydia Allden, of Woodhouse, Ely.

Gamgee—Clark.—On the 22nd inst., at Stamford-hill Congregational Church, Arthur Gamgee, M.D., F.R.S., of Brackenbury, Professor of Physiology in the Owens College, Manchester, to Mary Louisa, second daughter of James P. Clark, Esq., of London and Montreal.—No Cards.

Kelly—Hyde.—On the 8th inst., at Holy Trinity Church, Yeovil, Charles Kelly, M.D., to Florence, daughter of the late Rev. Wm. Hyde.

Spence—Crosse.—On the 15th inst., at St. James's, Piccadilly, J. A. W. Spence, L.R.C.P.Ed., Madras Medical Staff (second son of John Spence, F.R.C.S.), to Fanny Louisa, youngest daughter of the late Edmund Crosse, Esq., of Fairfield, Harrow Weald, and Ladbroke-gardens, Bayswater.

DEATHS.

Bindon.—On the 31st of March, at Guy's Hospital, John V. Bindon, F.R.C.S.I., aged 60.

Clapperton.—On the 18th inst., at Prestwich, Geo. Clapperton, L.F.P. & S. Glas., aged 36.

Dell.—On the 14th inst., at Chiswick, E. C. Dell, M.D., aged 56.

Hardwick.—On the 11th inst., at Axbridge, John Hardwick, M.R.C.S.E., aged 70.

Helsham.—On the 14th inst., at Mile-end-road, Arthur Helsham, Surgeon (in practice prior to 1815), aged 90.

Lane.—On the 15th inst., at Tullow, Co. Carlow, Thos. B. Lane, M.B., aged 62.

Rolf.—On the 10th inst., at South Shields, A. G. Rolf, M.R.C.S.E., of High-street, Gateshead, aged 45.

Shorland.—On the 16th inst., at Weymouth, G. Shorland, M.R.C.S.E., aged 67.

Spyers.—On the 14th inst., at Faversham, Thos. C. Spyers, M.D., aged 38.

Willing.—On the 15th ult., in India, suddenly, Harry Brutton, only surviving son of Dr. Willing, of Great Wakering, Southend. To the great grief of his parents.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*]

Notes, Short Comments, and Answers to Correspondents.

The Care of Lunatics.

An illustration of the difficulties and anxieties connected with the medical supervision of the insane may be found in the last Report of the Physician-Superintendent of the Royal Edinburgh Asylum for the Insane. Dr. Clouston, after drawing attention to the unusually large number of persons admitted suffering from melancholia, comments on the strength of the suicidal tendency in some of the patients. The ingenuity, determination, and persistence of the propensity in a few were very remarkable. One patient tried to swallow everything he could lay his hands on, from the ink used by his fellow-inmates of the ward to write their letters, to small stones, eighty-two of which he swallowed one day, and apparently was none the worse for them. He picked out nails from the woodwork, and tried to push them into his heart, and starved himself so persistently that he had to be fed with a stomach-pump. Two attendants were constantly with this patient. Another man gave quite as much trouble. After a time the intensity of the malady subsides. Chronic patients are to be seen working as shoemakers, joiners, &c., and having access to cutting weapons, who on admission were highly dangerous.

Practitioner.—It is a matter which rests entirely in the hands of the authorities of the institution, and we must decline to give an opinion on the case.

Poisoning by Milk.

To the Editor of The Lancet.

Sir,—In your journal of July 10th I read an interesting article on Poisoning by the Milk of Goats which had browsed upon colchicum. There is a possibility of cows' milk also conveying this poison to the human subject; for in May last, when on a visit to Shropshire, near Downton Castle, I saw a meadow in which the Colchicum autumnale was very abundant, and I learned that a few days before a valuable cow had died of gastro-intestinal irritation, caused by its feeding upon this acrid plant.

I remain yours truly,
H. M. Duncan, M.D. Lond.
Buckingham-Palace-road, S.W., July 15th, 1875.

Sanitary Service in War.

The mortality of the French wounded, says M. Wyrouboff in the June number of the *Philosophie Positive*, was double the mortality of the German wounded in the late war. This result was due simply to the defective sanitary organisation of the French.. The German army, out of a total effective of 914,000 men, lost 17,570 killed, 10,717 dead in consequence of wounds, 12,174 dead by disease, and 4009 missing—making a total of 44,460 dead. The wounded amounted to more than 127,867. M. Wyrouboff does not enumerate the sick. The mortality of the wounded, therefore, was 8·3 per cent. For the French army the data are not so detailed; the number of killed, dead from wounds and disease, is not indicated separately, and the tota effective remains unknown. We have, however, the number of the sick In round numbers the killed, dead from wounds and from disease, were 117,475 (without counting the 119,065 dead in captivity in Germany, and during *internement* in Switzerland and Belgium); the wounded were 131,000; the sick and congelés, 339,421. The total mortality of the wounded and sick together was, therefore, 24·8 per cent. The number o the wounded, it will be seen from these not quite perfect data, was nearly the same on both sides—the proportion being maintained in all circumstances, even when the two armies were almost equal in number, as at Metz, where the French lost during the whole campaign 42,500, and the Germans 44,200. Another striking point is the large total of sick and the enormous mortality. In effect, supposing the number of killed equal to the number of Germans killed (which is probable), the equality of the number of the wounded being given, and taking into consideration that (save small-pox) no epidemic prevailed, then the 100,000 deaths divide themselves very unequally between the sick and the wounded. With the documents in hand, it would be difficult, not to say impossible, to determine with precision the mortality of the sick and that of the wounded; but we have in this direction some data of value. The three great ambulances of the French Society, which had among them 2768 wounded, show a general mean of mortality of 14·5 per cent. Now, those three ambulances, says M. Wyrouboff, "étaient du petit nombre de celles dont l'installation était à peu près convénable." At Metz the mortality exceeded 15 per cent.; in a great number of ambulances installed round Sédan it reached 20 and even 27 per cent. Without exaggeration, therefore, the imperfect figures at our command enable us to say that the mortality of the French wounded was double that of the German! M. Wyrouboff's paper is well worth study, as showing the anxiety of the French to make their sanitary as effective as their combatant service.

Mr. J. V. Solomon.—We shall be very pleased to receive them.

"The Odd Shilling."

To the Editor of The Lancet.

Sir,—I am a general practitioner, and, like most of my class, have experienced the *res angusta domi*, although I now begin to flatter myself that that is a thing of the past. I still fret, however, under unjust burdens.

For the last three years I have on an average attended 100 midwifery cases a year, with fees varying from £1 1*s.* to £3 3*s.* For the sake of illustration let us take the minimum fee of £1 1*s.* The above should thus show a return of £105; yet I find I have only received £100. How is this? Simply owing to the objectionable custom of turning over the odd shilling to the nurse. Who originated this custom? Can nothing be done to put a stop to it? I have myself tried hard for some time past to put a stop to it, but have had only very partial success. What was at first given as a favour seems now to be demanded as a right, as many of the nurses have point-blank asked for the odd shilling, and to conciliate them I have been fain to yield. I think I have thus incurred odium by not giving spontaneously, and if so, then, *à fortiori,* must I have incurred a greater degree of odium from those to whom I did not give at all. This could not be were the custom universal among medical men to pocket the silver as well as the gold. The nurses are paid for their services. Why then should we be expected to supplement their income from our already too hardly earned fees? Further, I have not noticed (with one exception) that physicians and surgeons remit the odd shilings on receipt of their fees. Why should general practitioners be thus saddled with this indefensible burden? We are perpetually crying out about the onerous State taxes, yet we voluntarily impose one on ourselves as burdensome as any of those. The odd shillings in my confinements would nearly pay both my income and assessed taxes in their present reduced rates. The axiom, "Take care of the pence, and the pounds will take care of themselves," seems to be ignored in our profession.

The above subject has been frequently ventilated of late in your columns. But there is another matter akin to this that I have not seen referred to by anyone. I am frequently asked to vaccinate gratuitously the babies of those patients I have delivered, and I invariably refuse. I am often told that this is the practice of many other medical men. Surely this is the acme of generosity, and shall I say, too, the acme of folly? When the State now provides for the gratuitous vaccination of all children, can there be the slightest excuse for private practitioners doing this work gratuitously? I think not, and I hold that any practitioner who does so is acting unjustly to his professional brother. Anyone who can afford to pay £1 1*s.* for delivery can surely afford to pay 2*s.* 6*d.* for vaccination.

I am, Sir, yours &c.,
London, July, 1875. J. B.

Waterclosets.

A correspondent calls our attention to the paucity of waterclosets in lodging-houses, and states he knows houses with twenty or thirty lodgers, and only one watercloset for the whole number. The evil pointed out is productive of ill consequences in many ways. Medical officers of health should invariably insist that sufficient accommodation in this respect shall be provided in all houses which their duties compel them to enter. It is but a short time since we received a letter from a clerk in a Government office, complaining of very great remissness on the part of the authorities. The accommodation in his office was disgracefully bad and insufficient.

SERIOUS OCCURRENCE AT THE GENERAL HOSPITAL AT GHENT.

ALL the internes, externes, assistants, and substitutes (house-surgeons, house-physicians, dressers, &c.) of this hospital have just left *en masse* under the following circumstances:—It would appear that one of the physicians or surgeons, in consequence of some dispute, the cause of which is not mentioned, called out to the young gentlemen, "You are all fools" (cretins). Thereupon they, being deeply offended, wrote to the hospital committee demanding an apology, and stating that, in the event of a refusal, they would adopt decisive measures. The committee answered that the letter was rude and threatening, and that no notice would be taken of it. Thereupon the students announced that they would quit the hospital; and, in order to avoid any detriment to the patients, they would stay for three days to allow them to obtain substitutes. After this interval the whole of them vacated the hospital, and the committee at once applied to the other students, but no one would accept the advantageous terms that were offered. The practitioners of the town were afterwards applied to, but only four responded, which is a small number to take the place of between twenty-five and thirty students. *L'Union Médicale* extracts these facts from *Le Scalpel*, and observes that such a conflict, such insulting language on the part of an official, and the obstinacy shown by the committee, could hardly occur in Paris.

Mr. David Gibb, (Airdrie.)—The matter shall receive attention next week.

OPERATION ON A HORSE UNDER CHLOROFORM.

To the Editor of THE LANCET.

SIR,—A successful piece of equine surgery, having some interest for members of our ranks, may be worthy of record in your journal.

The subject of this notice is a foal of the cart breed born near this town. He had a rudimentary fifth leg growing from the middle third of the metacarpal bone of the off fore-leg, reaching nearly to the ground. The upper part of the rudimentary leg was an expansion of the true "cannon" bone; at the fetlock joint it possessed a separate articulation, having long and short pastern bones, also a hoof, the whole being about nine inches in length.

This *lusus naturæ* was a patient of my friend, Mr. R. A. Stock, veterinary surgeon, of this town, whose opinion was sought as to the advisability of amputation. His opinion, and one in which I coincided, was that there was a fair chance of success in the operation.

On June 4th, the foal then being five weeks old, a fine, healthy, well-developed, and powerful animal, was placed by me under the influence of chloroform, and Mr. Stock commenced operating by making a long incision nearly the whole length of the small leg; the integuments were thrown back, exposing the whole abnormal growth. The knife was then passed through the joint, two sesamoid bones were dissected out, and a protuberance of the true cannon bone was sawn off with a small bow-saw from below upwards. Several vessels required tying; the integuments were brought together with wire sutures, and the whole of the lower part of the limb was enveloped in a wet bandage. About three ounces of chloroform were required, which nearly proved fatal. Cold water thrown over the head and friction applied to the body, however, speedily restored animation.

Since the operation not a single bad symptom has supervened, the after-treatment consisting of the application of cold water and carbolic-acid lotion. When the sutures sloughed away, the parts were kept in place by bandaging. Four weeks after the operation the wound had quite healed, and the little animal is now as lively as possible, without lameness or stiffness of the fetlock joint.

The point of interest about the case is the apparent impunity with which cold steel can be made acquainted with the joint of an animal, both in the form of scalpel and saw, and the reflection is whether individuals of our own species of the same tender age could go through the same operation with the same impunity. I am, Sir, yours obediently,

Lewes, July 9th, 1875. JOHN G. BRADEN, M.R.C.S.

M.D., (Edinburgh.)—1. We have not heard of there being any assessors; but it is probable that, on an examiner being dissatisfied with a paper, he submits it to the judgment of his *confrères.*—2. We think there must be a good many vacancies; but our correspondent should apply to the Director-General of the Medical Department of the Navy.

Enquirer.—Not legally, but a prosecution could not be sustained.—2. He could not hold such an appointment.—3. We do not know of any such handbook.

A STUDENT'S GRIEVANCE.

To the Editor of THE LANCET.

SIR,—May I be allowed to draw your attention and that of your readers (among them the Council of the College of Surgeons) to the very great length of time that is allowed to elapse between the preliminary examination and the notification of the result to the candidates. This year the examinations were held on the 8th, 9th, and 10th of June, and the results were not made known until to-day, close upon five weeks after. Moreover, this delay, always irksome, is rendered still more so by the authorities not stating some definite time for the communication of success or failure, and by the statement on the official card, to the effect that "the result of the examinations will be made known in about *three weeks.*" As a consequence, one is kept in a state of feverish excitement from the expiration of that three weeks until the card arrives. Now, when we remember that the University examiners, with at least as many candidates, and a far greater range of questions, can make their report upon a previously fixed time within nine days of the conclusion of the examination, does it not seem rather curious that the College of Perceptors cannot put the men out of their misery in less than five weeks? I feel sure that each of the three hundred or so young men who have been kept in suspense for the last few weeks will echo my sentiments when I say that it is a most miserable time; that if absolutely necessary, it is deplorable; and if unnecessary, it is—well, to put it mildly—very hard. I cannot but think that if the attention of the authorities were drawn to it, we might expect some improvement. Yours obediently,

Croydon, July 13th, 1875. C. H. D.

CHEAP PILLS.

THE Charity Organisation Society's *Reporter* publishes an extraordinary letter from a venerable correspondent, now domiciled in a country workhouse. It is a confession of the tricks he played upon a too credulous public while assisting a peripatetic medicine vendor. It is pretty well known that the nostrums which are hawked about the country by the lowest grade of quacks are made up of the very cheapest material that can be used, and it may be said that, as a rule, no deleterious ingredient ever finds its way into mixture or pill. Large fortunes have been made out of bread pills and of water coloured with a little burnt sugar. Whisky and water and gin and water, again, have taken well when coloured. The famous "Balm of Gilead," which brought immense wealth to its illiterate inventor, was composed of gin in which cardamoms had been steeped. There was, however, in patent pills the trouble of rolling the farinaceous matter of which they were made, and it was left for the itinerant doctor whose career is chronicled by our contemporary to obviate this labour. He simply went to a rabbit-warren or sheep-fold, where he found ready-made pills. These excremential products were coated with sugar, put in boxes, and warranted to cure all diseases, and not to contain any of the poisons regularly used by medical practitioners. His receipts, on an average, from the sale of these pills were £10 a week.

M. Hirst.—We regret we cannot assist our correspondent in the matter. We would advise her to advertise in one of the daily papers.

THE INDIAN MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—In your frequent notices of the medical services you seem not to be aware of the great discontent that pervades the ranks of the Indian medical service. The new Medical Warrant that you lauded so highly on its promulgation in December, 1864, has proved to be a delusion and a snare.

The pay and emoluments of the Indian medical officers are much less than they were a quarter of a century ago, notwithstanding the depreciation in the value of money since then, and the increase made to the pay of other branches of the Indian services in consequence.

Present rules press hardest on the very junior and on the comparatively senior members of the service (those under five and those over fifteen years' service). The former, having been "unemployed" (in the pay office sense) during their first two to four years, may consider themselves lucky if they be clear of debt at the end of their fifth year's service; while the latter, having returned from furlough, married a few years previously, find themselves at fifteen years' service, with a rising family to educate, on only 800 rupees a month, with no prospect of being able to retire on a higher pension probably than £365 a year; for there is no longer a Retiring Pension Fund, and not more than one man in ten can possibly qualify for the deputy surgeon-general's pension.

The changes indicated are—the abrogation of unemployed pay to all except those *bonâ-fide* unemployed; the increase of pay of surgeon-majors to 1000 rupees a month at fifteen years' service, with an increment of 50 rupees a month yearly till the attainment of 1500 rupees a month as a maximum; medical officers in civil employ to be put on a separate roster, to have their pay assimilated to that of civil servants, and to be, in fact, placed under the same rules as other military officers in civil employ.

The retiring pensions require to be nearly doubled, and to be made available after seventeen, twenty, twenty-five, and thirty years' service, instead of at the periods now in force. The additional pension for service in the grades of deputy surgeon and surgeon-general should be proportionately available at the end of each year's service, instead of only in a lump sum at the end of the full five years' service, as now. Yours &c.,

June, 1875. PROGRESSUS.

LOVELL *versus* BEHRENS.

THE report of this trial for the recovery of fees has reached us, and we congratulate Mr. Lovell on his success. The subject will receive our special attention next week.

Dr. McRae, (Penicuik.)—We cannot at present call to mind the published cases of such an injury. If our correspondent will run over the index numbers of THE LANCET volumes, he will probably meet with what he requires.

"DROSERA."

To the Editor of THE LANCET.

SIR,—I have not yet had an opportunity of thoroughly reading Mr. Darwin's monograph on the "Insect-eating Powers of the Drosera," and am, therefore, not able to say if he has made any mention of a short note on the subject contained in Dr. Withering's "Systematic Arrangement of British Plants," published in 1801. If he has not, I am sure that he will pardon me for drawing the attention of those interested in the subject to the notice contained under the heading "Drosera," which was written seventy-four years ago, but which only pointed out as probable what Mr. Darwin has demonstrated in so clear a manner. Dr. Withering seems to have failed to produce artificial contraction of the outer leaves; but this was probably because he only scratched them, and did not allow the irritating substance to remain for a sufficiently long time on the plant. This is, I believe, in accordance with Mr. Darwin's experience. The following extract will show that his friend Mr. Whately, probably by more careful manipulation, succeeded better: "Few persons can have observed the Drosera in its native bogs without seeing some of the leaves doubled up; but the cause of this, I believe, was first ascertained by my friend Mr. Whately. In August, 1780, that gentleman, being upon a visit in Derbyshire, and gathering some specimens of the Drosera, examined some of these folded leaves, and, finding a dead insect in each, was prompted to irritate the upper surface of other leaves by touching them with a pin. The effect was a sudden contraction," &c. &c. He goes on to mention several other experiments performed by himself and others; but I have already trespassed too long on your valuable time, so will add no more, but am,

Yours truly,

Penge, July 14th, 1875. WM. DOUGLAS STRANG, M.R.C.S.

Moribund Patients and Death Certificates.

Mr. W. C. Matthews.—The case is not free from difficulty. Our correspondent did right in stating that his attendance on the patient only meant one visit, and that but seven hours before death. Where a medical man is not called in till the patient is moribund, and yet it is evident that the illness has been of some duration, it is almost right to decline to certify. The question of negligence has to be tried in such a case, and this can only be done by a coroner. A medical man exists, not to certify the cause of death, but to prevent the occurrence of death; and if a fair chance is not given him, he should indicate the same either by withholding the certificate or appending a note of the fact. We assume that our correspondent saw no signs of violence, or, doubtless, he would have referred the case to the coroner.

Glass-lid Coffins.

To the Editor of The Lancet.

Sir,—In your impression of the 3rd instant several of the advantages were stated which would be obtained by adopting a system of burial in which the lids of the coffins were made of glass.

In addition to these it may be pointed out that in medico-legal inquiries these coffins would be very useful. In cases of death from burning, from the knife or firearms, from falls from heights, from railway and machinery accidents, from drowning where some time had elapsed before recovery of the body; in all cases, in short, where the body had been much injured or decomposed, coffins of this sort might be used. The glass in such cases would not be painted over till after the inquest; but deodorants, as recommended, could be placed around the body without obstructing the view of it. The duty of the jury would be rendered much less unpleasant, and the feelings of relatives would not be outraged by the coffin being forcibly broken open for the formal purpose of viewing the remains.

As regards decoration of the coffin, this system would be also of advantage. Designs of various kinds could be executed on the glass, and over the face a tint could be given, which would relieve the ghastly colour of death. Or, leaving the glass quite clear, we could strew flowers, real or artificial, over the body, and place wreaths or festoons of these on the coffin outside. We could cast flowers and fresh leaves on the coffin in the grave, and thereby do away with the thought of rough substances coming in contact with the body on the breaking of the glass-lid. When flowers and leaves were not to be had, straw, hay, or shavings might be used for the purpose. Under this plan, also, the sooner would our decaying bodies pass into the freshness and blossom of leaf and flower.

It is strange that the glass-lid has not been adopted in this country in cases where it is not intended to be broken, as here advocated. It has been so used in America, and in several countries with hot climates, for which it is well suited. The remarks that have been made are intended to show that it has many advantages which should lead us to adopt it. If, however, we really wish to employ a plan that will speedily dispose of the dead, and yet not hurt the feelings or health of the living, we must make use of the glass-lid that will easily break, and allow the departed to lie at once in the bosom of our mother earth. I am, Sir, yours truly,

Redcliffe-gardens, S.W., July, 1875. Colin Henderson.

Major-General Shaw, (Portsoy, Banffshire.)—Our correspondent is thanked for drawing our attention to the article. While we must venture to doubt the correctness of the theory as to there being any connexion between the practices to which our correspondent alludes and the occurrence of canine rabies, we concur with him in condemning the cruel custom of mutilating animals, by cropping their ears and tails, under the absurd idea of improving their appearance.

Army Medical Service.

To the Editor of The Lancet.

Sir,—As the state of the army medical department is now under consideration, a few words from an unsettled young surgeon will, I hope, be pardoned.

The pay in the British army is fair, and the work I suppose in time of peace moderate. What strikes one as the great drawback is the expensive mode of living. This, I believe, under the present system is unavoidable. To men with private means it may be acceptable; but probably the majority of men who would wish to enter are not thus situated—in fact, this is the reason why a good many of them have not attempted private practice.

If a separate army medical department were established, I understand the men would live altogether outside the barracks to which they were attached, and that there would be one general uniform for all. If this were the case, the army would hold out great attractions to me, and no doubt to many others also, and I do not see how efficiency would be diminished.

It has been assumed that under the regimental system a sort of social glory is reflected on the army surgeon. This must be difficult to appreciate. Though I spent some time in a large garrison town, I have failed to observe any particular superiority in ordinary combatant officers over ordinary medical men. I remain, Sir, yours &c.,

London Hospital, July 20th, 1875. M.R.C.S. Eng., L.R.C.P. Lond.

A Guy's Student.—Niemeyer's Medicine; and our correspondent would have the advantage of a good translation to compare with his own.

Mr. Ryott.—The letter has been forwarded to the gentleman named, who, no doubt, will give his attention to it.

The following paragraph is taken from the *Methodist Recorder* of July 9th, which we think should receive world-wide circulation:—

"The New Surgical Mode of Extracting Cancer without the administration of chloroform or the aid of the amputating knife, with an account of seventeen examples of the improved treatment, which have been selected from ninety-eight cases of successful operations, out of which number only three recurrences of the disease have taken place. By Dennis Turnbull, M.D., LL.D., Licentiate of the Royal Colleges of Physicians and Surgeons, Edinburgh; 16, Cambray, Cheltenham. Post free for 13 stamps, of the Secretary to Dr. Turnbull's Dispensary (for local poor only), Mr. Wm. A. Norman, 9, Promenade-villas, Cheltenham, which is under the management of a Committee, President, Vice-President, and Treasurer. For full particulars see the Pamphlet. N.B. Under this treatment patients sleep well, and enjoy their daily drive or walks. A stamped envelope will secure special references to persons who have been cured."

The Faculty of Nancy.

Much activity has of late been displayed in the construction of the buildings necessary for carrying on the studies. Several lecture-rooms have already been given up to the pupils, and it is expected that by November the Faculty will be in good working order. As the law for allowing the founding of Faculties by private enterprise is now passed, the official teaching will probably be carried on with the utmost zeal. Competition will stimulate the old and privileged bodies to exertion, from which much good may be expected.

Poor-law Relief.

To the Editor of The Lancet.

Sir,—In reply to "Justice" in your impression of last week, allow me to state that he is only a ratepayer. If R. be destitute he should apply to the relieving officer, who should, in emergency, give a medical order and relief, which the guardians would pass at their next meeting; if not urgent, the application should be put before the guardians at their next meeting. If R. can and does pay for professional attendance, he cannot be regarded as destitute, professional assistance being out of all proportion more valuable than food. The guardians elect a medical gentleman to attend and report on the destitute sick, and it would produce great confusion, and not uphold the position of their medical officer, if they recognised any other medical authority (especially such as is obtainable at five farthings a week). The guardians are not guided by any opinion expressed by "Justice," but by that of W., the gentleman selected by them, and approved by the Local Government Board. Yours &c.,

Framlingham, July 19th, 1875. Geo. E. Jeaffreson, Guardian.

To the Editor of The Lancet.

Sir,—R., the patient, *quâ* the doctor, is an independent gentleman, who not only pays his doctor's bill, but pays it in advance. On representing this to the guardians, "Justice" will find that the Board will release their own doctor from attendance, although they will require a certificate from him that the man is totally disabled. "Justice," whatever his qualifications may be, is unknown to them, and they cannot give out-door relief on his authority. At the same time I do not believe they can make W. attend him. A similar case has occurred to me on three occasions, and the guardians have invariably acted as above, and made the club doctor do the work for which he is paid. W. would be glad enough to leave the case in the club doctor's hands, and sign the necessary certificates. "Justice" must be very hard up for work to wish to retain such a case. Perhaps if he will see the relieving officer himself, he will find the man's statement exaggerated.

Yours truly,

July, 1875. Parish Doctor.

Mr. Henry George Dixon.—The system of medical qualification in the United States is very loose and unsatisfactory. A good English practitioner in the far West would, we imagine, be a great boon, though we cannot say how far the profession is overstocked. If our correspondent will read an article in The Lancet of Jan. 9th, he will gather some information as to the way in which medical education and qualification are managed in the States.

Unqualified Medical Practitioners.

To the Editor of The Lancet.

Sir,—With regard to the above subject, the amended Act respecting registration of deaths might be made of much greater use if duly qualified and registered medical men would take the trouble to sign the initials of their qualifications uniformly, and not write such vague indications as "Surgeon," "M.D.," &c.

The registrars of births and deaths are not supplied with a list of the registered medical practitioners in their respective districts, which should devolve either on the Medical Council, or should be attended to by the Local Medical Associations which exist in most localities; but the medical practitioners, in self-defence, should at least make the district registrars acquainted with those persons who are supposed to be unqualified, that inquiries respecting them might be made.

The making or "causing to make" a false entry in a register book of deaths is a misdemeanour; and as the name and the initials of the medical practitioner are now inserted in the books, I have no doubt it would be easy to obtain a conviction against a person assuming to be a duly registered practitioner. But all these precautions are perfectly useless while qualified practitioners consent to give certificates to oblige men who have not incurred the expense and trouble of a legitimate medical education.

I am, Sir, your obedient servant,

July 20th, 1875. W. H. Butterfield.

Mr. J. F. Porter.—We do not think any good would accrue from the publication of our correspondent's letter.

Dr. Tattersall, (Clayton-le-Moors.) — The last edition of Carpenter or Kirkes; Aitken, Watson, Reynolds's System, or Ziemssen's Cyclopædia of Medicine; and Ringer's work on Therapeutics.

Quæsitor.—The Lancet of February 28th, 1874.

Incorrect Illustrations.

To the Editor of The Lancet.

Sir,—Mr. Spencer Wells, in his argument that "a specific morbid poison must, under all conditions, produce identity of results," uses, by way of analogy, this illustration—viz., "If you sow a grain of wheat you do not get barley or oats; the seed germinates, and you get the same variety of vegetable produce." Now, it is a fact which has been demonstrated by experiment that, under certain conditions, wheat may be made to produce rye; oats may be converted into barley. Dr. Lindley says: "In orchidaceous plants, forms just as different as wheat, barley, rye, and oats, have been proved by the most rigorous evidence to be accidental variations of one common form, brought about, no one knows how, but before our eyes, and rendered permanent by equally mysterious agency." Mr. Wells will, therefore, see that his illustration would have been more useful to Dr. West, Dr. Greene, and others, who contend that the set of symptoms which we call puerperal fever may be caused, under proper conditions, by mental emotion, cold, typhus, typhoid, erysipelas, &c. Your faithful servant,

Sydenham, July 17th, 1875. A Darwinite.

Mr. James Murphy.—The appointments to the public medical services—the British and Indian military and the naval services—are obtained by competitive examination. The colonial appointments are in the gift of the Colonial Office, to which application must be made. Besides these, there are appointments under the Local Government Board and the Home Office. Our correspondent will find much information on the subject in the Medical Directory.

Egbert.—We are unable to answer our correspondent's question. He should consult his solicitor.

G. H.—We believe the question has been decided in the negative.

THE BATHING SEASON.

To the Editor of THE LANCET.

SIR,—Eastbourne was this morning the scene of a very exciting event, which might have proved fatal but for the bravery of a medico, assisted by two of the bathing men. Two girls were bathing, and got out of their depth, one sinking. Immediately a cry was raised. The two men and the doctor plunged into the water, and up to their necks before reaching the drowning girls. One was fainting when brought ashore; the other nearly dead, but I think ere this has recovered, as she received every attention from the hands of her rescuer, who, of course, was drenched from head to foot. I heard, but have forgotten, the doctor's name. I have taken the trouble to address you for two reasons—first, that I think a boat ought always to be waiting on the bathers to prevent such a catastrophe as might have occurred, and more especially to show the Eastbourne Board the necessity of having one off the pier, where bathers swim every morning, without the least chance of being saved if an accident were to happen to them; and for the second reason, to applaud the bravery of a member of the medical profession. Your obedient servant,

July 20th, 1875. OBSERVER.

COMMUNICATIONS not noticed in the current number will receive attention in our issue of the ensuing week.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. G. Johnson, London; Dr. Pollock, London; Mr. Hutchinson, London; Dr. D. Powell, London; Mr. Goyder, Bradford; Mr. Foster, St. Albans; Mr. Solomon, Birmingham; Dr. Smith, Loftus-in-Cleveland; Surgeon-Major Keeds; Mr. Worthington, Benson; Dr. Handfield Jones; Dr. Taaffe, Brighton; Dr. Matthews Duncan, Edinburgh; Mr. Hirst; Mr. Jeaffreson, Framlingham; Mr. Owen, London; Dr. Scott; Mr. Gordon, London; Mr. Oliver; Dr. Gill; Mr. Yeld, Lucknow; Mr. Ellis, Newcastle-on-Tyne; Dr. Collin, Harlington; Mr. Thompson, Lincoln; Dr. Porter, London; Mr. Colman, Brompton; Mr. Cumming, Stirling; Mr. Sutton, London; Mr. Adams, Lymington; Mr. Lloyd, London; Mr. Rogers, Canterbury; Mr. Murphy, Sunderland; Mr. Walker, Norbiton; Mr. Philpot, London; Dr. Tattersall, Accrington; Dr. M'Rae, Penicuick; Mr. Fowke, London; Mr. Parker, Bath; Mr. Gould, London; Mr. Hornibrook, London; Dr. Fraser, Edinburgh; Mr. Glyn, London; Mr. Payne, London; Mr. T. H. Mead, Christchurch; Mr. Deeley, Malton; Mr. Hodges, Leicester; Mr. White, London; Mr. Gray, London; Dr. Decroix, Lyons; Mr. Butterfield, London; Dr. Roosa, New York; Dr. Ryott, Newbury; Mr. A. Sutcliffe, Dunham Massey; Mr. Cresswell, Dowlais; Mr. Smith, Deptford; Mr. Roberts, London; Mr. Benfield, Leicester; Messrs. Calvert and Co., Manchester; Dr. Savage, London; Dr. Edis, London; Mr. Tilsley, Burslem; Dr. Lyon, Glasgow; Mr. Hunter, Bombay; Dr. Hardman, Blackpool; Mr. Purvis, Maemhouse; Mr. Whetford, London; Mr. Lanneman, Tunbridge Wells; Mr. Gwynne, Wotton-under-Edge; Dr. C. Black, Oban; Rev. J. Thomson, Bridge of Allan; Mr. Cowell, London; Mr. Jolly, Penrith; Mr. Gibb, Monkland; Messrs. M. and J. Medical Diary for the ensuing Week.

Monday, July 26.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.

ST. MARK'S HOSPITAL.—Operations, 9 A.M. and 2 P.M.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ST. PETER'S HOSPITAL. — 3½ P.M. Expected Operations: Three Cases of Lithotrity.

Tuesday, July 27.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 3 P.M.

Wednesday, July 28.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. MARY'S HOSPITAL.—Operations, 1¼ P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at 1½ P.M.

GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.

LONDON HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2½ P.M.

Thursday, July 29.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

Friday, July 30.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1¼ P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, July 31.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NOTICE.

In consequence of THE LANCET being frequently detained by the Post Office when posted for places abroad *more than eight days after* publication, subscribers and others are reminded that such copies can be forwarded only as book packets, and *prepaid* as such.

TERMS OF SUBSCRIPTION TO THE LANCET.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year	£1 12 6	Six Months	£0 16 3

TO THE COLONIES AND INDIA.

Lectures
ON SOME
NERVOUS DISORDERS THAT RESULT FROM OVERWORK AND MENTAL ANXIETY.

By GEORGE JOHNSON, M.D, F.R.S.,
PROFESSOR OF MEDICINE IN KING'S COLLEGE; PHYSICIAN TO KING'S COLLEGE HOSPITAL.

LECTURE II.

Gentlemen,—In my last lecture I referred to some of the more common sources of mental and nervous disorder. In the present lecture I propose to describe some of the consequences or symptoms which may result from overwork, anxiety, or mental shock and terror.

The effects of mental anxiety vary greatly in different cases, the difference depending partly upon the original mental and bodily constitution of the patient, partly upon education, position in society, and habits of life, and very much, too, upon the kind of treatment to which the anxious patient is subjected. But amidst all the variety of circumstances to which I have alluded there are certain general features which characterise nearly every case of overwork and mental worry. These general characters I now proceed to describe.

Amongst the effects of anxiety of mind, whatever may have been the exciting cause, there is not one which is more frequent or more important than that which manifests itself by sleeplessness or by disturbed and therefore unrefreshing sleep. It is very interesting to note the various accounts which different sufferers give of their sleeping hours. One of the most frequent complaints is that the sleep is disturbed by distressing and frightful dreams, which assume a great variety of forms in different cases. The sleeper often fancies that he is falling down a precipice or into deep water, or that he is pursued by some fierce animal in brute or human form, or that he is in some situation of difficulty, perplexity, and danger from which he cannot escape: these are amongst the mildest forms of unpleasant dreaming. In other cases the dreamer has visions of dead relations and friends, or he is haunted by spectres of every form which a disordered imagination can conceive. No physiologist can doubt that in dreams such as these we have the explanation of most stories of ghosts and apparitions. Samuel Taylor Coleridge, who, as we know, at one period of his life was a large consumer of opium, when asked if he believed in ghosts, replied, "No, I have seen too many of them myself." The distress of the dreamer is often manifested to those who are watching his slumber by a pained or terrified expression of countenance, sometimes by profuse perspiration, with violent action of the heart, and laborious or hurried and gasping breathing; sometimes, too, by suppressed moans, or by frequent talking, and not uncommonly by a loud cry of terror. In some cases the dreamer starts out of bed and walks about the room, and he may awake in doing this, or he may be aroused by his own cries; but in other instances, as in the case (No. 2) which I related in my last lecture, it is very difficult to bring him back to a state of complete consciousness. On awaking he often has a vivid recollection of all the circumstances of his dream, and he fears to go to sleep again lest in his sleep he should have a return of the dreadful thoughts and visions; but in other cases he is quite unconscious that he has been dreaming or talking or making a noise; he has only a vague sense of something terrible, and he finds his skin bathed in perspiration and his heart beating violently. This violent palpitation is sometimes a source of great alarm to the patient. I was once called up to one of our medical students, whom I found in a paroxysm of hysteria, with globus in his throat and a dread of instant death. He had led a very quiet life, but he was of a nervous temperament, and had been anxious about an approaching examination. It appeared that he had been dreaming, and when he awoke he found his heart beating violently; this alarmed him, and as he continued to direct attention to his heart, the palpitation increased in violence; this, again, added to his fears, and thus afforded a good illustration of the mutual influence upon each other of mind and body, of head and heart. I found that he had no symptom of structural disease of any kind, and after some time, but not without considerable difficulty, I succeeded in persuading him that he was only in a fright, and that his fears were groundless.

When a patient awakes after a night of disturbed sleep, such as I have described, he usually complains of exhaustion, and will often say that he is more tired in the morning than when he went to bed; a feeling which we can easily understand if we bear in mind that not only has he had no rest—a dreaming brain being an unresting brain,—but he has been exposed to the disturbing and exhausting influence of terror during the greater part of the night. This sense of languor and unrest is in most cases combined with loss of appetite, inability for exertion, depression of spirits, a sensation of pain or weight in the head, and sometimes with an oppressive feeling of drowsiness during the daytime, particularly after meals.

When this restless condition has continued for some time it is almost invariably associated with a peculiar, anxious expression of countenance, and, in particular, with a remarkable appearance of the eyes, which will often enable you at once to detect the general character of the case with which you have to deal, and so will suggest such further inquiries as may be necessary for its complete elucidation. The appearance of the eyes to which I refer is difficult to describe, but it may be immediately and easily recognised when once it has been pointed out and clearly perceived. The anxious eye loses that brilliancy and liveliness upon which so much of its natural beauty depends, and it assumes something of the dull and inanimate appearance of a snake's eye. The iris often appears to be in a more or less fixed and inactive condition, so that the size of the pupil varies but little and slowly under the influence of light or mental emotion. If you watch the bright eyes of an intelligent child under the influence of some pleasing emotion, you will see that there are frequent and rapid changes in the size of the pupil. The dull and anxious eyes of the overworked and harassed man or woman are in striking contrast with the brilliant eyes of the happy child. In cases of long standing the pupil is often very small; and, in some of the worst cases, I have seen the pupil contracted almost to the size of a pin's point. It is seldom that even in these extreme cases there is any intolerance of light; but there is often, in a greater or less degree, dimness or defect of sight, without any appearance of structural change in the eye. I believe, however, from what I have seen, that atrophy of the optic nerve and retina is one of the more serious consequences of long-continued overwork of brain. Quite recently I have seen a very intellectual girl, aged nineteen, who, as a result of excessive mental application in addition to other signs of nervous disorder, suffered from severe *pain* in the eyes, which prevented her from reading. An eminent oculist had examined her eyes, and pronounced them to be free from all appearance of structural change.

I have already intimated that the anxious expression of the patient's face will often give a clue to the general character of the case, and serve as a guide to the true source of the symptoms. I may add, too, that the information which we gain by observing the patient's physiognomy will sometimes induce us to persevere with our inquiry when the answers to our first questions are not such as we expected to receive. For instance, I have often been told by patients who have presented the anxious expression of face which I have described, that their sleep is not only not bad, but indeed they "sleep too well." Now in these cases it will often be found, on inquiry, that although they sleep so heavily that they can with difficulty be aroused in the morning, yet their sleep is constantly disturbed by frightful dreams; consequently they awake unrefreshed, and they are languid and drowsy during the day. The cure for this too heavy but unrefreshing sleep is a dose of chloral or some other soporific at bedtime, repeated for a few nights until the habit of dreaming is broken; the result will often be refreshing sleep at night, and, as a consequence of this, the cessation of the languor and drowsiness which had before continued during the day, after a night of harassing dreams.

I have sometimes been told, in answer to the question

No. 2709.

whether a patient has been disturbed by dreams, that he does not get sleep enough to render dreaming possible. He declares that he lies awake all night. I believe, however, that a patient is very rarely so wakeful as this statement would imply; and that often when he supposes that he has not once closed his eyes he has really slept, but his slumbers have been so frequently broken and disturbed by dreams that he can scarcely distinguish between his sleeping and his waking hours. I scarcely need say that sleep of this imperfect character is almost as unrefreshing as complete wakefulness.

I have yet one remark to make with reference to the character of the dreams. When the exciting cause of the anxiety and restlessness has been some great grief or sudden shock of terror, it will often happen that this continually recurs to the dreamer. Thus the bereaved mother not only dreams of her dead child, but the image of her lost one often appears vividly before her in her dreams. The alarm of fire will be repeated every night for months; and the poor man whose case I related in my last lecture (Case 2) appears to have been terrified during a period of seven years by the nightly recurrence of the ghastly vision of the child whose violent death he had accidentally caused and witnessed. In many cases, however, it is impossible to trace any resemblance between the character of the dreams and the past events of the patient's life.

One of the consequences of mental anxiety, which is as often as any other associated with disturbed sleep, is a more or less complete loss of the appetite for food. In only a very small proportion of the many cases that I have seen have I been told by an overworked, anxious, dreaming patient that he could take his food as usual. In many instances the digestive powers are much impaired; there is pain or a sense of weight or fulness, with flatulence, after eating. In some cases severe stomach pain, with water-brash and occasional vomiting, are complained of; in others diarrhœa is a troublesome symptom. Now I am careful, and I warn you to be careful, not to confound with the cases to which I now refer, others of a quite different kind. I mean cases of dyspeptic and nervous derangement, principally caused by an excessive indulgence in alcoholic stimulants, and a deficiency of nutritious food. Again, there is another class of cases in which dyspeptic symptoms have been excited, or at any rate aggravated, by a too liberal administration of stimulants to some weak and nervous patient who has been exhausted by bodily fatigue, or mental worry, or by an attack of illness. A weak and nervous patient who takes wine, beer, or spirits freely, because, as he says, he has no appetite for food, should be warned that the first step towards the recovery of his appetite and his strength must be an entire suspension or a greatly reduced supply of alcoholic stimulants, and the substitution of milk or some other easily digestible liquid food, until the power to eat and digest solid food is regained.

Returning now to the more immediate effects of mental anxiety, it is not easy to determine whether the loss of appetite is a direct result of the nervous excitement, or whether the restlessness is a result of the diminished supply of nutriment to the brain; but it is probable that the two conditions have a mutual influence upon each other. Probably most persons have experienced in some degree the power of mental emotion to take away the appetite for food and to disturb the process of digestion. On the other hand, the influence of an empty stomach or of a sense of hunger in preventing sleep, and of a moderate fulness of that organ in promoting drowsiness, is well known. One fact which I have frequently observed tends to show that in the class of cases under consideration the loss of appetite is a direct result of a primary disorder of the nervous system: I allude to the beneficial influence of opium. A man who has been more or less restless for many months, and who during that time has had almost a loathing of food, after taking a grain of opium at bedtime for a few nights, sleeps soundly for several hours, and then wakes with an appetite for food; refreshing sleep returns each night, at first with, but soon without, the help of opium, and with this the appetite often becomes voracious, like that of a patient recovering from a fever or from some other exhausting illness. Now it is contrary to all clinical experience to suppose that opium would by any direct influence on the stomach increase the appetite or assist digestion. The tendency which opium has to disturb the stomach and to excite sickness or nausea is one of its disadvantages, which renders it on the whole a less useful soporific than chloral in this class of cases. This well-known disturbing influence of opium on the stomach, and the fact, which I have observed in numberless instances, that the appetite has not returned until the opium has procured sleep, tend to prove, as I have said, that the derangements of the nervous system, in the cases referred to, are first in the order of time and importance, while the loss of appetite and the impaired powers of digestion are consequences of the nervous disorder.

Now let me point out to you that in cases of delirium tremens the order of events is the opposite of that which I have just now described. The delirium and other evidences of nervous disorder are indirect results of alcoholic excess; they are directly due to malnutrition of the brain. I must remind you that the delirium which is caused by the presence of alcohol in the blood—the delirium of intoxication—is entirely different from what is called "delirium tremens." An attack of delirium tremens generally follows a more or less prolonged fit of drinking, during which very little food of any kind is taken, so that the brain and the tissues generally are for a time poisoned and starved simultaneously. Up to a certain point the frequent repetition of the alcoholic stimulus tends to steady the tremulous muscles and to calm the excited brain; but at length the supply of drink is cut off by want of cash and credit, or it may be that the abused and irritated stomach will tolerate no more; then, when the stupefying influence of the alcohol has passed away, the unhappy man awakes to a consciousness of his condition—his money gone, his work neglected, debt and perhaps disgrace incurred; and so, under the influence of a perturbed mind and a starved brain, he has a fit of delirium tremens. Now we have learnt by degrees that the main object of treatment in these cases of delirium *e potu* is not to attempt to force on sleep by large doses of opium or chloral, but to feed the delirious patient. In spite of all treatment by drugs, the wakefulness and the delirium will continue until a certain amount of nutriment has been assimilated by the starved and exhausted brain. Opium and chloral, and even alcohol, cautiously given, are valuable aids; but the substitution of narcotics for food has often been attended with a rapidly fatal result, as I have shown at length in my lecture on Delirium Tremens (published in THE LANCET, April 21st and 28th, 1866). You see, then, that, while in cases of delirium *e potu* sleep follows and is favoured by taking food, in the cases primarily nervous the soporific effect of opium or chloral procures sleep, and then restores the appetite and assists digestion.

Now, to continue the history of our nervous cases, it is obvious that the combined influence of loss of sound refreshing sleep and loss of appetite, with imperfect digestion, must tend to impair the nutrition and lessen the strength. Loss of flesh and strength to a greater or less extent are observed in almost every case when the symptoms have been of long duration. One man who had suffered much from restlessness and frightful dreams, in consequence of business anxieties, assured me that, during a period of two years, his weight had been reduced from 15 st. to 11 st.; and this statement appeared quite consistent with the loose fit of his skin and his clothes. Another man, who had suffered in a similar way in consequence of misfortunes, had lost, as he informed me, from 2 st. to 3 st. weight in two years. This was one of the cases before referred to, in which, after a long period of nearly total inability to eat or to digest food, a voracious appetite became almost a matter of complaint after refreshing sleep had been obtained by the temporary use of opium. Another patient, a woman, who had suffered from anxiety, restlessness, and loss of appetite for several months, had diminished in measure round the waist from 24 in. to 19 in. After taking a grain of opium at bedtime for a few nights she slept well, and began to eat so voraciously that, as she told me, she felt ashamed to eat so much, and her husband was quite anxious about her great and, as it seemed to him, unnatural appetite. The result was that within a month she had gained 3 in. in measure round the waist. These measurements were her own; but the rapid improvement in her appearance was quite confirmatory of her statement. It is obvious that so considerable a defect of nutrition as I have here indicated must react injuriously upon the mental disturbance in which it originated. For there can be no doubt that the depressing and disturbing influence of mental motion will be, *cæteris* *paribus*, in direct proportion to the degree of bodily exhaustion, and more particularly to the malnutrition of the brain. A sure way to excite delirium or other serious form of nervous disorder would be to take an over-anxious nervous man and to bleed or purge or starve him, and thus reduce rapidly his bodily powers. It is painful to think how often and how fatally this mode of practice was adopted when it was supposed that furious delirium was the result of inflammation of the brain or its membranes, and that the proper treatment consisted in the fearless adoption of so-called antiphlogistic measures. And antiphlogistic they certainly were in the literal sense of tending often to *extinguish the flame of life*.

The derangement of digestion, to which I have referred as one amongst the most common results of mental anxiety, not unfrequently gives rise to symptoms referable to the urinary organs—symptoms which often excite an unfounded dread of serious organic disease. Frequent micturition and pain in the back are the symptoms usually complained of, and these are often supposed by an anxious patient to depend on disease of the kidneys or bladder, more especially when the urine is turbid and deposits a copious sediment. On examination it is often found that the urine is excessively acid and deposits lithates on cooling. The acid urine irritates the kidneys and bladder, and thus occasions the pain and the frequent micturition. In other cases the urine is neutral or alkaline, with a copious phosphatic sediment. These states of urine are, of course, not peculiar to nervous and anxious patients; but, since any pain or any unusual appearance of the urine is a source of alarm to these timid subjects, you ought to be prepared to give a correct explanation of the symptoms and to apply the appropriate remedies.

In some instances the pain in the back is very severe, and being much increased by motion, its seat is probably in the lumbar muscles; but I have met with several cases of this kind which have been mistaken for inflammation of the kidneys and treated as such. One of my hospital patients, a carpenter, had severe pain in his back, which he thought was caused by inflammation of the kidney, for he had a similar pain some months before, which was called inflammation of the kidney, and for which he was treated by cupping and other active measures. On that occasion he was ill for several weeks. He had a very anxious countenance, he had been for some time out of work, and he was restless at night. I gave him an opiate pill for a few nights, which made him sleep well, and he quickly lost his pain. He told me that the first attack of pain, like the last, had come on when he was anxious on account of being out of work; I therefore concluded, as he did, that both attacks were of the same kind. He agreed with me, too, in opinion that the opiate plan had been far more successful than the antiphlogistic treatment adopted on the first occasion. Many pains in the loins are quite unconnected with nephritis, and, on the other hand, the kidneys may be seriously diseased without a complaint of backache. A chemical and microscopical examination of the urine is essential for accuracy of diagnosis in all cases of suspected kidney disease. I have seen several cases in which saccharine urine and other symptoms of diabetes have apparently resulted from excessive brain-work and mental worry. This would seem to be analogous to the result of Bernard's well-known experiment on rabbits, in which the secretion of saccharine urine was directly caused by mechanical irritation of the medulla oblongata.

There is, probably, no form of functional disturbance which is a more frequent source of anxiety and alarm to a nervous patient than the palpitation of the heart which is so often associated with mental anxiety and restlessness. I have already referred to palpitation in connexion with the frightful dreams by which the patient is harassed at night. A similar disturbance of the heart's action is scarcely less distressing in the daytime. The cause of this is probably in part purely physical, and partly mental. The nutrition of the heart suffers in common with that of the rest of the body in consequence of broken sleep and the associated disorder of the digestive organs. The tendency to palpitation thence resulting is similar to that which exists in cases of anæmia and chlorosis. The powerful influence of mental emotion upon the heart's action is so well known that it is unnecessary to insist upon it. It will commonly be found that the disturbance of the heart's action bears a relation, first, to the weakness and consequent irritability of the organ itself, and, secondly, to the degree in which the patient's attention is anxiously directed towards the heart. The two main objects of treatment, therefore, are to strengthen the muscular tissue of the heart by sleep, food, and tonics; and to divert the patient's attention from his heart by the assurance that there is nothing in the state of that organ about which he need be anxious. The effect of a favourable opinion and a hopeful prognosis is often very beneficial by calming the patient's fears and restoring his confidence; while, on the other hand, an erroneous diagnosis or an unguarded expression with reference to heart disease may be a source of great additional suffering to the patient, and may greatly retard or entirely prevent his recovery. A poor woman whose natural irritability and nervousness had been increased by great domestic troubles, and who, in consequence, suffered much from palpitation, was told by her medical attendant that she had a diseased heart, and an issue was established over the supposed seat of disease. She had endured this addition to her sufferings for several weeks when she came to the hospital. The impulse of the heart was sharp but feeble, and the sounds were quite normal; there was evidence of a weak and irritable heart, and of nothing more; but it was long before she lost the dread of sudden death, which had taken complete possession of her mind, and which had doubtless been confirmed by the erroneous diagnosis and the injudicious treatment to which I have referred.

It is but seldom that an irregular and excited action of the heart is unassociated with some degree of difficult breathing, and when this is attended with cough an anxious patient will often be tormented by a dread of consumption.

I make frequent allusion to the fears of this class of patients because they constitute so very important a feature of their history, and because it should be one of the chief objects of the physician to convince the anxious patient that his fears are groundless, and that the disease which he so much dreads has no existence except in his own terrified imagination. If, after a careful examination of the chest, we can assure him that his lungs and heart are sound, we shall remove a weight of anxiety from his mind which will greatly contribute to the recovery of equanimity and bodily strength.

Hunterian Lectures
ON
SYPHILIS,
AND ON
SOME LOCAL DISEASES AFFECTING PRINCIPALLY THE ORGANS OF GENERATION.

Delivered at the Royal College of Surgeons of England,

BY HENRY LEE, F.R.C.S.,

PROFESSOR OF SURGERY AND PATHOLOGY TO THE COLLEGE.

INOCULATION OF SYPHILITIC BLOOD—(CONTINUED.)

M. ROLLET has collected together and tabulated twenty-seven cases in which syphilitic inoculation was performed on patients who had not previously had the disease. Of these the inoculated matter was derived from primary chancres in eight cases, and the average period of incubation before the appearance of any distinctive syphilitic symptoms was about twenty-four days. In ten of the cases the secretion inoculated was derived from mucous tubercles, and the average period of incubation was nearly the same. From this it appears probable that the disease, whether derived from a primary or secondary source, runs the same course in uncomplicated cases. Now in all the instances hitherto given the first appearances have been those belonging to the adhesive form of inflammation. This I regard as the typical mode of the origin of the disease, where there is no accidental cause of irritation, and where the system is infected for the first time.

Jenner long ago warned the profession against supposing that every inoculation produced from a vaccine vesicle conveyed the vaccine disease. That which did he has carefully described. It is essentially the product of the adhesive form of inflammation. The lymph produced which is fit for reinoculation contains no pus, and, indeed, to the common eye, and even with a microscope of low power, appears to contain no globules. Dr. Beale has, indeed, shown that with a microscope of high power germinal matter may be detected in the vaccine lymph, and in the processes of scabbing and healing no doubt real pus-globules are often formed. But this in no way militates against the fact that the essential character of the action which produces the lymph that in its turn will reproduce the same disease is of the adhesive and not of the suppurative nature. How imperfectly these two actions, so clearly defined by Hunter, have been considered by many continental writers, is demonstrated, in reference to our present subject, by the indiscriminate use they make of the words "vesicle" and "pustule." In many of their writings the "vaccine pustule" is as often mentioned as the "vaccine vesicle." The two kinds of action produced by syphilitic inoculation have, in the same way, been confounded and spoken of as if they were the same and might produce the same results. The works of many continental and of some English authors are full of the descriptions of the origin and course of the so-called syphilitic pustule, of the number of times it may be reproduced, of its value as a means of diagnosis, and the effects of its repeated reproduction on a patient's constitution. Now this form of inoculation is quite distinct from that which we have hitherto considered as having to do with the production of real syphilis. These specific pustules, as they are called, no more resemble real syphilitic inoculations than the abnormal pustules which sometimes follow attempts at revaccination resemble in their pathological effects the morbid process which protects a patient's constitution against the recurrence of the same disease or against the infection of small-pox.

The cases hitherto given all occurred in virgin constitutions, or in those who had not previously had syphilis; and in them we have the opportunity of recording the disease as developed in healthy patients, and in an uncomplicated condition. The actions both in the primary and secondary manifestations originally commence, if they do not terminate, without suppuration, ulceration, or mortification. The disease commences by an effusion of lymph, which becomes organised, and may remain so. The corresponding inguinal glands are affected with the same kind of action. They enlarge, but never suppurate, as I believe, from this disease alone. The subsequent eruption of the skin, again, is of the same nature. First, congestion of capillaries, with some slight formation of new matter; and then different forms of pimples, smaller or larger, distinct or confluent. These all desquamate, and are often covered by scales as thin as silver paper. In their separate and isolated form they have received the name of lichen; when larger, of tubercles; when confluent within a defined space, although distinct at first (as they may be generally observed), the eruption assumes the forms of psoriasis and lepra.

Upon a recurrence of the disease at a later period, or even at its first appearance, in an unhealthy person, the secondary manifestations, instead of being of the adhesive character, may directly present the distinctive characters of suppuration, ulceration, or mortification. These facts did not escape the acute observation of Carmichael; and he accordingly describes (1) the papular venereal disease, (2) the pustular venereal disease, and (3) the phagedænic venereal disease. It is true that he attributes these to different kinds of poison; but that they are essentially the same, and depend upon one and the same disease, appears evident from all these varieties sometimes appearing, as may practically be observed, upon the same person, and from the same infection, at different periods. In particular states of the constitution of the patient there can be no doubt that a primary affection, which would present any of these varieties, would be very likely indeed to be followed by secondary manifestations of the same character.

Thus, in Group vii., Nos. 220, 221, and 222, in our collection, are represented an eruption of papules and of tubercles, the latter passing into suppuration and ulceration.

No. 226 is a coloured lithograph of the forearm, showing a pustular syphilitic eruption. The distribution of the pustules has a corymbous character, and the eruption presents the progressive stages of papule with pustular summit, fully developed pustule, and encrustation with a deep brown scab. In their mature form, and especially in their incrusted stage, the pustules are surrounded with a slightly inflammatory areola. The patient was a young man, aged eighteen, of strumous diathesis, subject to enlarged lymphatic glands, and exposed to vicissitudes of temperature. And the order of succession of the disease was as follows:—In October, a chancre; eight weeks after, a pustular eruption, with periosteal swellings; a month later, sore-throat, with tonsillitis; six weeks after this, a second eruption of pustules; and three weeks afterwards a third and partial pustular eruption.

No. 227 is a plaster cast of the forearm of the same patient.

No. 228 is a model of the forearm, exhibiting a pustular form of syphilis in a retrogressive stage. The surface is sprinkled over with papulæ in various stages of decline, and with a group of thick brownish-yellow scabs; the largest of the scabs measures nearly half an inch in diameter, and a denuded tubercle one-third of an inch.

Both the primary and secondary manifestations of disease may thus be most materially modified, either by constitutional or local causes, or by the tissue in which they appear. The principal constitutional cause which modifies the first appearance of a real syphilitic inoculation is the existence of what I have, for want of a better term, called the syphilitic fever. This fever is recurrent in its nature, and its consequences will often appear after the lapse of months or years, but its effects are manifested in the most marked manner on its first occurrence. Under the influence of this fever, I need not remind my present audience that eruptions in great variety will appear on the skin, without any local irritation being applied; but if, in addition, there be local irritation, a circumscribed spot of inflammation may be determined which the local irritation alone would not have produced. Thus the inoculation of common pus, which, under ordinary circumstances, would have produced no effect, may give rise to a pimple, a tubercle, or a pustule. If the pus so inoculated should contain any irritating matter, then we have the joint effect of the constitutional disease determined to the part, and the local irritation produced as the immediate effects of the inoculation. The way in which the existence of the syphilitic fever in its various degrees modifies a real syphilitic inoculation is a point which, I believe, has not hitherto been sufficiently considered.

The following cases afford some illustration:—

Case 31.—A medical student had a typical chancre, which, in all probability, had something like the usual period of incubation. He inoculated himself from what secretion he could get from its surface, before it had become indurated: the inoculation succeeded—a pimple formed, in the apex of which a small quantity of white lymph appeared, which soon became softened down. Both inoculations subsequently became well developed button-shaped chancres. In this instance, as in the second inoculation in Case 18, the inoculation was performed while the syphilitic fever was in process of being developed. It had the effect of doing away with the usual period of incubation, but not of preventing the typical induration, which it certainly would have done had the inoculation been performed at a later period, as has been recently so abundantly proved by the so-called process of syphilisation.

Case 32.—A woman who had for some years been about town, but who had no present symptoms of constitutional syphilis, was inoculated with the secretion from an infecting sore; a pimple followed the inoculation; at the expiration of a month the pimple was still there, and was surrounded by a faint copper-coloured eruption. The spots occupied the diameter of about six inches, and faded ultimately of their own accord; no other local or constitutional effect appeared as the result of the inoculation. Here the syphilitic fever, as I read the case, was so far exhausted as to have no power of itself of producing fresh manifestations, but had left an impression upon the system which protected it from any fresh constitutional disturbance, and, at the same time, very materially modified the local symptoms. During the existence of the syphilitic fever—that is to say, as long as the patient is liable to fresh manifestations of disease from his first infection—the inoculation of the secretion from a primary or secondary unirritated syphilitic sore generally produces no result, or a slight superficial irritation which soon subsides, or some abortive form of adhesive inflammation. Inoculations of this sort are analogous to those performed with the vaccine matter on patients who are still under the influence of a previous vaccination. I have over and over again inoculated syphilitic patients with the secretion from an uncomplicated, unirritated, indurated chancre, and always with a negative result. If, however, from any constitutional or other cause, there be much irritation about the parts from which the secretion so inoculated is taken, then a result is produced. But it is very different from those which we have previously considered. If, for instance, an indurated sore be irritated by the application of some savine ointment, as in my original experiments upon this subject, then the inoculation succeeds; or if the sore has been irritated by the application of any other diseased secretions, or if it be much inflamed from any constitutional or local cause, then again a result is produced; but that result differs in its essential characters from the typical syphilitic inoculation. There is no period of incubation. There is no well-defined induration produced. There is no enlargement of the corresponding inguinal glands, and no fresh constitutional symptoms. The inoculated spot shows at once the characters of the suppurative inflammation, and not those of the adhesive; any fresh matter that is effused rapidly softens and no longer remains a part of the living body. Unless some phagedænic action takes place there is little or no loss of the natural structure of the part, and when the inoculation heals the cuticle is on a level and sometimes above that of the surrounding parts. In this respect there is an essential difference, in my opinion, between this form of inoculation and that from the local suppurating sore, which I shall have hereafter to describe. In the same way secondary syphilitic affections, unless there be some constitutional or accidental cause of irritation, heal without loss of substance, and the cicatrices of the skin leave no permanent depression.

CASE 33.—Some matter taken from a patient who had a dense circumscribed induration on the inner prepuce, causing phimosis, accompanied by great discharge, and whose body was covered by a secondary eruption, was inoculated from a sore on the abdomen of another patient. A series of seven inoculations were produced. These all commenced as pustules, and produced irregular superficial ulcerations, covered with thick crusts. The edges of the ulcerations were scarcely defined. When they healed the cuticle covering them was on a level with that of the surrounding skin, and the marks of the inoculations were soon entirely effaced, as those of a secondary syphilitic eruption would have been when cured.

The syphilitic diathesis, like the effects of vaccination, may wear itself out more or less completely, and then a fresh inoculation may take place, which may produce fresh constitutional results.

CASE 34.—A married gentleman unfortunately exposed himself to contagion. This was followed by well-marked primary syphilis, for which he was thoroughly treated under my own care. About the time when secondary symptoms might have been expected his general health failed. He lost flesh; was pale and depressed; a slight eruption appeared on the skin of one arm, which, under treatment, very soon subsided. He had no other specific symptom for seventeen years, when he again exposed himself. A small circular abrasion now appeared on the glans penis, which ultimately became developed into a small tubercle, desquamating on its surface, and continuing for many weeks. The glands in the corresponding groin became enlarged and painful. These symptoms were succeeded now for the first time with well-marked circular copper-coloured patches on various parts of the body.

Other cases of this second inoculation of constitutional syphilis I have elsewhere mentioned, and will not here repeat. I shall have to consider this subject again under the head of Syphilitic Enlargement of Glands.

One form of reinoculation, which I have not seen described or referred to by authors, produces a red raised pimple on the mucous membrane, depressed in its centre, and persisting for many weeks. The appearance presented is not unlike a single projection of the surface of a raspberry.

Another most important modification of the results of the application of syphilitic matter depends upon the structure to which it is applied. Hunter showed, as I have said, that the mucous membrane was capable of the adhesive form of inflammation. Lymph may be secreted on its surface as the result of great or prolonged irritation, or effused into its structure, and into that of the submucous tissue. As a rule, however, irritation of a mucous membrane produces suppuration, and the pus-cells are thrown off from the surface, together with any irritating matter that may be mixed with it. The mucous membrane does not then become permanently thickened, nor does it ulcerate. The newly formed bioplasts carry their life up with them and cease to be a part of the living being which produced them.

"It is an invariable effect," according to the Hunterian doctrine, "that when any part of an animal is irritated to a certain degree, it inflames and forms matter, the intention of which is to remove the irritating cause. This process is easily effected when it is on a surface whose nature it is to secrete, but when on a surface whose nature is not to secrete, it then becomes more difficult, and another process must be set up. This is not only the case in common irritations, but also in specific irritations from morbid poisons, as the venereal disease and small-pox. The variolous matter, as well as the venereal, produces ulcers on the skin, but when it affects secreting surfaces, a diseased secretion is the consequence, and this is different in different parts: on the tongue, inside of the mouth, uvula, and tonsils, the coagulable lymph is thrown out in the form of sloughs, somewhat similar to the putrid sore-throat; but in the fauces, and all down the œsophagus, a thickish fluid, in appearance like matter, is secreted. When irritation is applied to a surface whose cuticle is thin, and where there is a secretion naturally, as the glans penis, then it sometimes only irritates so as to produce a diseased secretion." (See Case 8.)

There are three ways, Hunter says, in which a chancre may be produced: first, by the poison being inserted into a wound; secondly, by being applied to a non-secreting surface; and, thirdly, by being applied to a common sore. But infection of a patient's system, Hunter held, might be and often was produced by a gonorrhœa independent of a chancre. He says the matter of a gonorrhœa will produce either a gonorrhœa, a chancre, or the lues venerea; and the matter of a chancre will produce either a gonorrhœa, a chancre, or the lues venerea. Now there can be no doubt that Hunter in his descriptions has confounded together several different affections of the urethra, and has classed them together under the common name of gonorrhœa. Yet he owns the difficulty of distinguishing these, and says—"We see many gonorrhœas that begin without any appearance of inflammation, and I have been very much at a loss to determine whether they were venereal or not, for there is a certain class of symptoms common to almost all diseases of the urethra from which it is difficult to distinguish the few that arise solely from the specific affection." That the very large majority of cases of urethral discharge do not depend either upon syphilis or gonorrhœa may be concluded from the simple consideration of the great variety of causes which will produce such affections. These will be more fully considered hereafter. But if it be conceded that some forms of urethral discharge are really syphilitic, it is no easy matter always to distinguish them from those that are not. Inoculation has been supposed to furnish the means of diagnosis.

THREE CASES OF DILATATION OF LYMPHATIC RADICLES.

BY C. HANDFIELD JONES, M.B. CANTAB., F.R.S.,
PHYSICIAN TO ST. MARY'S HOSPITAL.

CASE 1.—W. S——, aged nineteen, fetler, admitted on January 11th, 1875. Family history good; father, mother, brothers, and sisters alive and well. No history of previous illnesses. About six weeks ago he had slight catarrh and cough, and noticed a small swelling of his neck. This was soon followed by swelling of the left side of the face and of the upper part of the head and forehead. It then appeared in his hands, and afterwards in his feet and legs. He had at the same time pains in the loins, which were not much felt unless he moved about. His urine at the same time was brown and thick and very scanty, and was passed very seldom. His appetite has never failed; his bowels have been pretty regular. He does not think he has lost flesh. Is anæmic-looking, but skin of trunk and abdomen is markedly brown, except a small patch near left iliac crest, which is white, the demarcation being abrupt between the pale and brown parts. Heart sounds are healthy. No anasarca, but the abdomen is markedly dull for some extent in both flanks, in the left especially; the dulness in left is diminished when he turns on right side. Urine: sp. gr. 1030, deposits red lithates, is highly albuminous. Has simple diet—milk, beef-tea; ordered chop; and, in place of fifteen minims of ipecacuanha wine, and one ounce of citrate of potash mixture, four times a day, which he has had for two days, he is now to have solution of perchloride of iron, fifteen minims, and acetate of ammonia mixture, one ounce, three times a day, taking one drachm of compound jalap powder every morning.

Jan. 18th.—Legs more anasarcous, feet pit markedly; both fundi very pale, discs not well defined; sight is good; he can read a paper.

Feb. 1st.—Urine pale, contains much albumen; deposits a light sediment, containing nothing definite.

18th.—Urine very scanty, loaded with albumen, sp. gr. 1040; pain in loins.

19th.—Left thigh and leg much swollen; the thigh measured 24 in., the right only 20 in. Pulse weak and small; vomiting; urine very scanty and turbid, turns almost solid when boiled, is thick with lithates when cool; deposits numerous slender homogeneous and granular casts, a few also containing some corpuscles.

20th.—Left leg still more swollen, depending part very hard; girth of thigh 25¼ in., left calf 16 in., right calf 12½ in. Right leg does not appear to be at all swollen. Pain is felt in left groin, not down the leg. Intellect quite clear. Urine not more than three ounces in twenty-four hours. Temperature 98·7° F.; pulse 96, weak. Has a warm pack every night.

22nd.—Marked dulness and absence of breathing in lower half, or rather more, of right back; a good deal of blood spit up. Scrotum very much swollen on both sides; right leg not swelled at all. Does not sweat at all in the pack; feels chilly. Urine: twenty-five ounces in twenty-four hours, sp. gr. 1040, thick with lithates. Taking, since the 19th, acetate of potash, half a drachm, in an ounce of water, three times a day and the mixture; hot-air bath.

25th.—Total urine 39 oz., of full colour, clear. A good deal more blood has been spit up. To-day the sputa are dark and muco-watery. Left thigh measures 25½ in.; scrotum still very distended.

27th.—Sweated last night very freely in the hot-air bath; the swollen leg sweated as much as the other.

March 1st.—Expectoration still very blood-tinged. Temperature 98°; urine, sp. gr. 1024, very albuminous. Gallic acid ten grains, glycerine twenty minims, water one ounce, three times a day.

3rd.—Much blood still in expectoration; thigh measures 24½ in.; scrotum more lax. Temperature before hot-air bath 100°, after bath lasting half an hour 100·4°. Skin of left thigh presents a great number of plexiformly arranged streaks running upwards.

11th.—The streaks are now evidently channels containing fluid; they have increased in size, and occupy a considerable extent both of upper and outer part of left thigh and buttock, and also the lower and inner part of the limb for a good way above the knee; they do not extend above the line of Poupart's ligament. They contain a clear alkaline fluid, devoid of corpuscles, slightly albuminous, sp. gr. 1009. A very large amount of this fluid ran from a single needle puncture; two clean sheets were saturated, and 1½ oz. was collected; the flow continued for some days. The expectoration on the 12th was nearly free from blood, and was less. The thigh measured 24 in., the calf 17 in.

On the 15th the total amount of urine was 47 oz. The lower right back only was dull, and a little crepitation was heard, and no other breath sound; the sputa were mucous and rusty. The dose of gallic acid was increased to twenty grains four times a day.

25th.—Left thigh measured 25 in., left calf 17½ in. The lymphatic channels at the upper and outer part of the thigh were so much enlarged that they often seemed to be on the verge of coalescing; some of them contained a red fluid. Smaller lymphatic channels were visible at the lower and fore part of left leg.

April 1st.—Thigh measures 26½ in., the calf 18 in.; left side of abdomen much swelled. The lymphatic channels are very prominent, and distended on upper and outer left thigh, and some have appeared in the same part of right; many of these contain a red-tinted fluid. The channels evidently indent or groove the corium, as is well seen when they are emptied by pressure.

19th.—Right leg has become swollen the last few days, and the scrotum increased; distended veins are seen on the scrotum, but none on the leg. Distended lymph channels are apparent now on upper and outer part of right thigh. Twenty grains of chlorate of potash, half a drachm of glycerine, and one ounce of water, three times a day.

23rd.—Fundus of both eyes pale. The urine, which on the 12th had been 20 oz., rose to 44 oz., on the 26th to 64 oz., on the 29th to 84 oz.

On May 3rd the urine still contained much albumen. There was much fluid in the abdomen.

24th.—Leg is diminishing in size; is bandaged. His general condition is good.

31st.—Urine very slightly albuminous, sp. gr. 1025; leg much smaller.

June 7th.—The leg is now nearly normal, save for the remains of the lymph channels, which are evident as depressions or grooves in the integument. Abdomen collapsed; resonant on right side, dull on left. Is able to walk about.

10th.—Came to hospital looking well, but requesting to have his chlorate of potash mixture, without which he did not feel so well.

Case 2.—Mr. ——, aged about forty-five, for many years a perfect hypochondriac. Always thin, but lately has emaciated greatly; has got cough and expectoration, and his lungs present unmistakable indications of softening tubercle; soft femoral vein swollen, firm, and tender; both feet and legs œdematous, with erysipelatous redness on left leg. On both feet, on the dorsal aspect, there are several enlarged lymphatic channels, extending from near the toes to about the ankles. These are quite like those described in Case 1. He died a few days after this note was made.

Case 3.—R. P——, aged nineteen, builder's labourer, admitted May 19th, 1875. Light hair and complexion, of slight make, hands of a dull red; a pale pressure spot is slowly effaced; he had scarlatina when a child; was not exposed to wet before his illness, but worked in a draughty place. Has felt ill three weeks; his face swelled seven days ago, and his legs and scrotum; the latter has subsided, the face continues puffed. Had sore-throat a month ago; it is not sore now. Skin moist; he perspired in a pack he had last night. Pupils very large. Vomits at times. Tongue furred, red at edges. Pulse 64; temperature 97·4°. Has pain on the right side, below liver, extending across to left. Abdomen full, dull in depending parts. Appetite good; is thirsty. Heart's sounds feeble; no bruit. Left lower back dull, and breathing very defective there; but resonance and breathing are present in the upper half of back. Lower third of right back is dull, and breathing weak; but no râles are heard. Urine: sp. gr. 1030, acid, highly albuminous. There is a congenital hydrocele on the right side; it became more marked four years ago, but he has always had some slight swelling in that region, which disappeared when he lay down. Retinal veins full and dark; the ocular fundi otherwise appearing normal. Simple diet: milk and beef-tea. To take ten grains of alum, twenty grains of sulphate of magnesia, ten minims of ipecacuanha wine, and one ounce of camphor mixture, three times a day; one drachm of compound jalap powder every morning.

May 22nd.—Urine in good quantity, dark with abundant sediment, loaded with albumen; sp. gr. 1032; deposits casts mostly narrow and granular, or homogeneous, slender, very few are corpuscular. Pulse feeble; feels very weak. Made sick by compound jalap powder. Omit pack and powder. Urine three ounces.

31st.—Urine yesterday had to be drawn off; this morning he passed it himself. Yesterday's urine is loaded with albumen, and deposits a notable sediment consisting of homogeneous casts, some narrow, others moderately wide, with abundance of medium-sized glomeruli; some casts consist of granular pigment; no blood-globules seen; ascites considerable. Temperature 97·4°; pulse 84.

On June 1st the urine was very dark, contained a large amount of blood; the corpuscles were numerous and distinct. On the 7th there was still much blood in the urine, the dropsy had increased considerably, the scrotum and prepuce were very much distended. On thighs and lower abdomen there were numerous distended lymphatic channels containing a more or less red fluid. These on the 10th were noted to run down to the line of Poupart's ligament from the integument of about the lower half of the abdomen. On the 16th they were very numerous on the thighs; those on the abdomen were larger, and contained much bloody fluid, which, examined under the microscope on one occasion, exhibited multitudes of red globules. Soon after erysipelas attacked the lower abdomen, the lymphatic channels discharged a very large quantity of serous fluid, he became very prostrate, the temperature rose to 104°, and he died on the 20th. No remedies appeared to be of any avail.

Post-mortem examination.—Lower extremities anasarcous; dilated superficial lymphatics on inner and outer side of both thighs; erysipelatous necrosis of skin of lower part of abdomen.—Thorax: Lungs non-adherent, slightly œdematous; bronchial tubes full of frothy secretion; a patch of apoplexy at base of right lung, great congestion at base of left. Heart healthy, except one or two minute patches of atheroma about aorta.—Abdomen: A large quantity of purulent-looking fluid in peritoneal cavity; under the microscope the fluid presented rather a small number of corpuscles, and those which were visible were smaller than pus-cells and less granular; some traces of peritonitis. Lymphatics well marked in mesentery in lumbar region; mesenteric glands enlarged. Neither receptaculum chyli nor thoracic duct enlarged. Left external iliac and common iliac veins, and the right iliacs at their junction and at the entrance into the inferior cava, were plugged with old organised clot; clot of more recent formation existed in the lower part of left posterior tibial veins. Liver, spleen, pancreas normal. Kidneys extremely hyperæmic, with smooth surfaces, cortical part enlarged, pyramids dark, some whity mottling in cortex; conjoint weight eighteen ounces; supra-renal capsules congested in their medullary portion. Ileum presented solitary glands very much enlarged; the mucous membrane was hyperæmic. The lymphatic glands in the groins and about Poupart's ligament were slightly, if at all, enlarged.

Remarks. — The special symptom which characterises these cases must be, I think, rare. I have not to my recollection met with it before. But little notice is found of it in authors. Hasse, indeed, says, when writing on septic inflammation of the lymphatics, that "during life we observe that the lymphatic glands become turgid, while the course of the lymphatic vessels is indicated by a network of flat red stripes." The last three words convey a better notion of the appearance seen in my patients than the descriptions given by some writers of cases of cystiform or general dilatation. Wilks and Moxon do not seem to have met with the alteration in question; they only mention the occurrence of great varicose distension of the lymphatics of the thigh producing cyst-like knots, in consequence of some more or less obvious cause of obstruction. Pelters (Schmidt's *Jahrb.*, vol. cxv., p. 183) records a case of remarkable dilatation of the lymphatic glands of the right groin, small and large intestine. The glands were converted into cyst-like cavities, tensely filled with a yellow fluid, and the afferent and efferent vessels were also much dilated. The cause of the dilatation was considered to be obstruction to the circulation from valvular disease of the heart, especially mitral stenosis, and cirrhosis of the liver producing considerable ascites. A case is reported from the clinique of Prof. Kussmaul (see *Medical Times and Gazette,* vol. ii. 1861, p. 119), where the lymphatics of the abdominal parietes were much enlarged. The patient was an old woman, who had been tapped several times for ascites depending on cirrhosis of the liver. "From the middle region of the abdomen a multitude of cord-like vessels of the thickness of quills, which looked like rows of pearls, and were much twisted and prominent, proceeded downwards towards both inguinal regions. In this course they gradually flowed into one another, and ended in a few large vessels of the thickness of the little finger, which disappeared in the inguinal region. These vessels commenced in the middle and upper part of the abdomen, in spots of different size, which were transparent, and not prominent; they were probably vessels flattened by great tension, and might easily have been confounded with the cicatrices to be found on the abdominal parietes after numerous pregnancies. These also existed in this case. The right diagnosis of these spots, which were not connected with each other, was in this case only made after the small (short?) but very wide canals had been discovered, which were filled with lymph almost to bursting. On puncturing these vessels a yellow, opalising, neutral fluid escaped, which contained a trifling quantity of albumen, and on one occasion showed an acid reaction." The legs were only slightly œdematous, and the lymphatic vessels of the lower extremities were not dilated. Kussmaul attributes the distension of the lymphatic vessels to the reflux of the lymph being prevented by the colossal accumulation of serum in the abdominal cavity; but he recognises the anomaly of the lymph vessels of the lower limbs not being dilated. The opinion of anatomists seems to be now pretty well decided that lymphatics originate in intercellular spaces, comprising under this term the spaces existing between the fasciculi of connective tissue, or between the elements of the tissues, and even the serous cavities. The lymphatic vessels are believed to open into the latter by orifices termed stomata.

Now the vessels which were so enlarged and apparent in my patients were certainly not the ordinary superficial lymphatics figured by Mascagni, for these run in the subcutaneous connective tissue beneath the corium of the skin, while those I noticed were quite superficial, and, though they grooved the corium notably, were either quite on its surface immediately beneath the epidermis, or in its more superficial layer. They appeared, in fact, to be rather dilated lymphatic radicles than actual vessels. But that they truly belonged to the lymphatic system cannot, I think, be doubted. For (1) the fluid in them was in pretty rapid motion, as shown by the quantity collected from a single puncture; (2) this fluid had quite the character of lymph; (3) the vasoid cavities, while observing a sort of plexiform arrangement, took a general direction upwards, and disappeared at the region where the superficial lymphatics pass down to join the deep—behaving, in fact, both on the surface of the abdomen and the thigh, like recognised lymphatic vessels do; (4) the venous obstruction which was present in all the cases affords a special reason for considering the fluid to be lymph, inasmuch as, the return of blood by the veins being barred, there was no other channel left for the fluid effused from the capillaries to take but the lymphatics.

But, admitting that the fluid was lymph, that the vasoid spaces containing it communicated with the lymphatics, and that venous obstruction had a very material influence in causing the formation and enlargement of these channels, I cannot but think that some other less evident cause must have been in operation. For obstruction of veins by thrombosis, or phlebitis, or pressure of tumours, is no uncommon event, and gives rise to considerable œdema, as in phlegmasia dolens, yet without any apparent distension of lymphatic channels. Perhaps, indeed, this does actually occur in all cases, or in most; but, inasmuch as the vessels affected are subcutaneous, and not supracutaneous or subepidermal, as in my cases, the alteration is not noticed. The peculiarity of my instances would then consist simply in the situation of the vessels or lymph-spaces affected by dilatation. The results of dissection in Case 3 are of great importance, as showing that pressure on the thoracic duct or enlargement of the lymph-glands may be quite absent in the condition we are considering. Conversely, it may be remarked that in the affection termed "adenia," characterised by great hypertrophy of the lymphatic glands, there is no dilatation of the afferent or efferent vessels. Grave disease of the kidneys existed in two of my cases, but caused anasarca only in one, so that this state cannot be credited with much effect.

Green-street, W.

VACCINATION GRANTS.—The following gentlemen have been awarded grants for efficient vaccination:—Dr. W. Hutchinson, Chipping Norton, £10 9s.; Dr. H. H. Phillips, Reading, £8 19s.; Mr. J. A. Bright, Glastonbury, £9 11s. (second gratuity).

ON THE TREATMENT OF HÆMORRHOIDS, AND THE COMPARATIVE MERITS OF THE OPERATION BY THE CLAMP AND BY THE LIGATURE.

By JAMES R. LANE, F.R.C.S.,
SURGEON TO ST. MARY'S HOSPITAL.

In a paper by Mr. Henry Smith in the last two numbers of The Lancet on the treatment of hæmorrhoids and prolapsus of the rectum by the clamp and cautery, founded on his experience of 400 cases, he alludes to certain criticisms of this procedure, and of his mode of advocating it, which have from time to time appeared. Amongst other things he says: "Just to show the extraordinary nature of the opposition which has been urged against the operation, I may state that one well-known surgeon wrote a long letter to The Lancet denouncing the operation. Luckily for me, but most unluckily for himself, the writer let it appear that he had never once made trial of the operation."

Finding that I am the surgeon alluded to, and that these observations refer to a paper published in The Lancet of Sept. 2nd, 1865, I feel it necessary to say a few words in reply, for the purport of my remarks is here completely misrepresented.

I have never "opposed" or "denounced" the operation with the clamp. In the paper referred to I was, on the contrary, very careful to disclaim all intention of depreciating it, believing it to be a sufficiently effectual method of dealing with the complaint, though I could not admit that it was better, and there was not a shadow of proof that it was safer, than a properly conducted operation with the ligature. My observations were directed against the unfair comparisons made by Mr. Smith between the two operations, and the extravagant laudations which he was constantly in the habit of bestowing on the one at the expense of the other—laudations which equalled, if they did not surpass, those which the profession had been accustomed to hear for some years previously from the same authority respecting the extraordinary merit of nitric acid in the treatment of this disease.

I also protested against the peculiar pathological doctrines enunciated by Mr. Smith in support of his views, when he asserted that "it is impossible for any surgeon conscientiously to tell his patient that there is no danger whatever after the ligature; but this may be *most truthfully stated* with regard to the operation with *my improved clamp*, if the most ordinary precautions are adopted to prevent bleeding." And again, when he said, "It is *not possible* that either tetanus or pyæmia, the two most formidable results of the ligature, can occur after this operation, because the condition which produces the former affection does not obtain—viz., the presence of an irritating substance round the nerves for several days; and pyæmia and other inflammatory affections will be effectually prevented by the exposed surface being deprived of its vitality and the veins being blocked up by the cauterisation." I ventured to point out that burns were a class of injuries by no means exempt from a liability to be followed by tetanus; and that it was an entirely new idea that the application of the actual cautery to cut surfaces was an effectual guarantee against pyæmia and "other inflammatory affections."

It is all very well for Mr. Smith to say, in effect, that as I had then never practised the operation with the clamp myself, I could not possibly know anything about it, and therefore that to any remarks of mine "no answer need be made." I submit, however, that it was not necessary to have performed this operation to appreciate the fallacy of the statements above quoted, or of the argument that, when a sloughing wound is made in the interior of the rectum with the actual cautery, the patient will be convalescent in one-third of the time required when a slough is made in the same situation with a ligature. I spoke, however, from the careful observation of a considerable number of cases operated on with the clamp by my colleagues. Since then I have repeatedly practised that method myself, and have witnessed it in the practice of others; but I see no reason, after ten years, to alter the opinion which I then expressed, that it is not safer or in any way better than a properly managed operation with the ligature.

The result of Mr. Smith's experience of 400 cases forms, without doubt, a very valuable contribution to practical surgery; and when we learn that out of this number he has only met with four deaths, it will, I trust, help to allay the vague apprehension which exists, even in the profession, respecting the risks attending operations for this disease. But I contend, at the same time, that he has not yet succeeded in demonstrating the superiority of the clamp and cautery over the ligature; and I do so on the following grounds. I have myself operated with the ligature, at St. Mark's Hospital and elsewhere, on more than 800 cases, with only three deaths; while Mr. Allingham, in his book published in 1871, states that he had then operated on 400 cases, without any death at all. With respect to pyæmia, no death from that cause has occurred in my experience, and Mr. Allingham states that 3210 cases in St. Mark's Hospital have not furnished a single example of it, though he refers to four cases of death from that cause in the practice of other surgeons after the operation with the clamp and cautery. I have no desire to maintain that the ligature possesses in this respect any peculiar advantage over the clamp, for I believe the tendency towards pyæmia will, in the long run, be found to be about equal in both; but the facts which I have stated effectually dispose of the peculiar immunity from pyæmia formerly claimed for the clamp by Mr. Smith, and also of his recently expressed opinion that "the complete sealing up of the vessels produced by the hot iron is the very best safeguard against pyæmia we can have." I am quite at a loss to see how vessels are more completely sealed up by cautery than by ligature; in fact, if the argument is worth anything, the ligature ought to be superseded by the cautery in surgical operations wherever practicable, in order to diminish the liability to pyæmic infection.

The most serious objection to the operation with the clamp is its liability to be followed by hæmorrhage. Mr. Smith himself now candidly speaks of this as "the result against which the surgeon has most to guard, and unless he takes very great care it is an occurrence very likely to take place." He mentions cases in which it took place to a rather serious extent immediately after the operation, and others in which it occurred a few days afterwards, when the bowels were relieved. In the latter it probably arose from the vessels being reopened in consequence of the slough being detached or disturbed during the passage of the fæces over the wounded surface—an indication that they are not so efficiently closed by cauterisation as when they are securely embraced by a ligature. A lesser degree of hæmorrhage seems to be not unfrequent, for we are told that "sometimes a good deal of blood is passed on the first action of the bowels, and on examination it is found that the greater part of this evacuation consists of dark coagulated blood, which had evidently slowly escaped into the bowel after the operation, and had remained there until the action took place," another indication that all the divided vessels are not completely closed by the cauterisation.

Were it not for the danger of hæmorrhage there would probably be little to choose between the two modes of operation; they are, in fact, only different ways of doing the same thing. From what I have seen I believe them to be as nearly as possible equal as regards the danger to life, and also as regards the ultimate result, the subsequent pain, and the time required for recovery; and I have seen nothing to justify the assertions that the method with the clamp is in any of these points superior to the other. But the danger of bleeding, which is confessedly a real one, is sufficient, in my opinion, on Mr. Smith's own showing, to justify the condemnation of the operation with the clamp in all cases where the disease is far advanced and large vessels are involved. One of the fatal cases which he records is significant. It is that of an elderly gentleman with very severe prolapsus. A very vigorous application of the cautery was necessary to arrest the bleeding, and the patient died on the fifth day from peritonitis. Mr. Smith does not doubt that the peritonitis was produced by the excessive employment of the cautery, and thinks it possible that he may even have injured the peritoneum. Surely in any case where there is a chance of such severe cauterisation being required, the operation with the ligature must be the safer of the two. I have myself never hesitated to use it in the most extensive cases of disease, and have never yet had occasion to repent having done so. I have only to add, in the words of Mr. Smith, slightly altered, that if he does not yet see the merits of the treatment by the ligature so clearly as I do, I can only hope that his conversion may arrive in time.

ON FATIGUE.

By G. V. POORE, M.D.,
ASSISTANT-PHYSICIAN TO CHARING-CROSS HOSPITAL, ETC.

THE recent discussion in the pages of THE LANCET on the effects of overwork, to which Dr. Wilks, Dr. George Johnson, and Dr. Savage have contributed their experiences, has induced the author of this paper to reduce his views on the same subject to a definite form, in the hope that they may prove interesting.

Work results in fatigue, and fatigue is a regular and constantly returning symptom experienced by all of us. Periods of functional activity invariably alternate with periods of repose, during which the waste caused by the exercise of function is repaired. We are indebted to Sir James Paget for having pointed out in his Croonian Lecture, delivered some years since before the Royal Society, that "rhythmic nutrition" is a law of nature; but, although the truth of this dogma is recognised on all hands, and may be said to be axiomatic, it has hardly received that careful consideration at the hands of practical physicians which it deserves.

Our whole life consists of a series of vibrations—periods of tension alternating with periods of relaxation; and, although the rapidity of these vibrations varies immensely, they are recognisable in all our acts, be they voluntary or involuntary. Let us look first to the "vibrations" of an organ the movements of which are placed entirely beyond our own control—the heart. Now, the rate of vibration of the heart is 72 per minute, and if the total period of each vibration be divided into ten parts, it will be found that four of these parts are devoted to the process known as *systole*, which may be looked upon as labour; three are occupied by the *diastole*, which, although hardly labour, is nevertheless exercise of function; and the remaining three parts are occupied by the *pause*, during which the heart apparently enjoys absolute rest from any exercise of function, and may be considered to be in a condition analogous to sleep. May we not apply the rate of action of this organ, which has been regulated for us, to our voluntary acts, and may not the heart be made to give the key-note, as it were, to many questions, personal and social? If we divide the day of twenty-four hours into ten equal parts, and give four of these to active work, three to functional exercise of other kinds, and three to sleep, we shall find that nine and a half hours' work, seven and a quarter hours' "relaxation," and seven and a quarter hours' sleep, is what a normal man may perform without injury to himself. "Eight hours' work and eight hours' play, eight hours' sleep and eight shillings a day," is said to be the dream of the trades unions, but, if they are guided by the heart, they ought to add an hour and a half to the period of labour, and take three-quarters of an hour from each of the other divisions of the day.

To continue with the consideration of our "vital vibrations," I may remark that it is universally ordained among civilised nations that once in every seven days there shall be a remission of labour and a change of occupation; and we further recognise the fact that it is highly advisable for those who are occupied in monotonous pursuits to break away from them at least once a year, and indulge in that variety of work which we call amusement. Monotonous repetitions of the same act are acknowledged, on all hands, to be the most potent causes of fatigue. "It aint the untin as urts im," said *Punch*'s horse-dealer, "it's the ammer, ammer, ammer on the ard igh roads;" and in this remark there was undoubtedly much practical wisdom which is very generally applicable.

Fatigue occurs directly we attempt to alter the rhythm of our vital vibrations by prolonging the periods of tension at the expense of the periods of relaxation, or by demanding for any length of time a quickening of the normal rate of vibration; and it is not unreasonable to suppose that every organ of the body has its "normal rate of vibration," if we could only determine what it is.

We recognise the fact that athletes who "over-train" run risks of cardiac troubles and loss of wind; that the man who, from any cause, is unable to sleep runs a serious risk of permanent impairment of health; and when we find patients pursuing their avocations too zealously we know that, if such offence against the laws of nature be persisted in, general paralysis or other form of "break-down" is likely to be the result.

Fatigue may be general or local, and both forms may be either acute or chronic.

That fatigue in all its forms is due to impaired nutrition there can be little doubt, and we shall find that the symptoms of chronic fatigue are often the prelude of definite and recognisable degenerative changes.

As to *general fatigue*, it is recognisable with ease both in its acute and chronic forms. There is a disability for performing either mental or physical work, and this disability is noticed first in work requiring attention and sustained effort, and, lastly, in those acts which have become automatic. The symptoms of general fatigue are referable usually to the brain and nervous system.

As to *local fatigue*, this, again, may be acute or chronic, and the symptoms of it are referable usually to the muscles; but we must always bear in mind that muscle and motor-nerve are one and indivisible, and that recent experiments have given great probability to the idea that every muscle is connected with a certain definite spot in the brain. When, therefore, we speak of a sense of fatigue we must necessarily be in doubt, notwithstanding the fact that the symptoms are referred to the muscle, whether brain, nerve, or muscle, one or all of them be really at fault. The symptoms of acute local fatigue are (1) *loss of power* to a greater or less extent. By too frequent or too prolonged stimulation the irritability of muscular tissue becomes exhausted, and it either refuses to respond or responds but feebly to the stimulus of the will; our power of adjusting the force of contraction to the act to be accomplished is lessened, and accuracy of movement and delicacy of co-ordination become impossible. (2) *Tremor* is a symptom of acute local fatigue, which everyone who has been called upon for extraordinary muscular effort must have experienced. (3) *Cramp-like* contraction is the symptom of local fatigue which disturbs our rest after a hard day's walking or riding, or muscular efforts in the ball-room or elsewhere. (4) The *pain* of fatigue is familiar to most of us, and is readily distinguishable from other forms of pain.

Local fatigue is caused far sooner by prolonged and sustained muscular effort than by repetitions of short muscular efforts having due intervals of relaxation between them. Anyone who has attempted to hold out a weight at arm's-length knows the impossibility of a long continuance of the effort, and it is proverbially true that standing in one position is to most people far more tiring than walking, the reason apparently being that in standing the muscles which support the body are subjected to a prolonged strain, while in walking we use the muscles on either side of the body alternately. The great increase of working power which we obtain by this alternating use of the muscles would seem to be one of the chief reasons for the bilateral symmetry of the body. Not only is sustained effort a far more potent cause of fatigue than repeated effort, but we find that, when fatigue supervenes, actions requiring sustained effort, be they physical or mental, are the first to fail, while automatic actions endure the longest, and in this respect local fatigue resembles general fatigue. It is quite possible to exhaust a muscle by artificial stimulation, and if one of the small interossei muscles of the hand be continuously faradised, it will be found that in a short time its power of contracting under any form of stimulus will be absolutely abolished. It is tolerably certain that the brain can have no share in artificial fatigue thus produced, and there seems good reason to suppose that in some people of energetic temperament the irritability of a muscle may be exhausted while the power of mental stimulation remains unimpaired.

Chronic local fatigue has causes and symptoms similar to those of acute local fatigue, and there can be little doubt that this condition is a common cause of many of those chronic maladies which seem to result from overwork, and which are characterised by irregular muscular action. That some cases of writer's cramp, torticollis, and hammer-palsy, are due to chronic fatigue of the muscles employed, there can be little doubt. Duchenne and Mr. Brudenell Carter have pointed out how, in cases of short sight, the prolonged strain of the internal recti has caused troubles of vision and even cerebral symptoms; and quite lately Dr. C. B. Taylor, of Nottingham, has shown reason for including in the category of "fatigue diseases" a peculiar form of nystagmus occurring amongst miners, who try their eyes by working in the dark, and the author has little doubt that, attention having been directed to the symptoms and effects of fatigue, additional light on the subject will be forthcoming.

Wimpole-street.

CONCLUDING REPORT
OF A
CASE OF INNOMINATE ANEURISM.

LIGATURE OF THE LEFT COMMON CAROTID ARTERY, FOR ANEURISM AT ITS BIFURCATION.

By FREDERICK ENSOR, M.R.C.S.,
SURGEON TO PORT ELIZABETH HOSPITAL, SOUTH AFRICA.

THE readers of THE LANCET of February 6th last will have noticed the report of a case of innominate aneurism treated by ligature of the carotid and subclavian arteries simultaneously. As it may be considered one of some surgical interest, and an example of a mode of treatment as yet on its trial, I think it right to publish the ultimate result of the case.

The operation was performed on Sept. 8th, and up to date of last report the man was going on favourably. The subclavian wound had firmly healed, and there was but a little stain of discharge from a granulating spot in the line of the carotid incision. The patient had little or no pain, the impulse was less, the bruit was less marked, and there was very trifling impediment to his deglutition, and he was allowed to go about the ward.

On Oct. 24th he very imprudently went out of his room with simply his night-dress on, remaining some half an hour out of his bed in the cold. The next morning he was taken with shivering, and had rheumatic-like pains generally. The pulse rose to 95, the impulse became very marked above the clavicle, and a little bleeding came on from the lowest part of the carotid wound. Ordered a mixture of carbonate of ammonia, chlorate of potash, and tincture of aconite, half a minim, every four hours.

Oct. 25th.—Pulse 88.

26th.—Pulse 80; impulse less. No pain.

27th.—Pulse 80.

28th.—Pulse 76. To take the mixture at eleven, four, and nine o'clock.

29th.—Pulse 76. Mixture at eleven and nine o'clock.

30th.—Pulse 75. Bowels too relaxed. To take two minims of tincture of aconite, twenty-five minims of chlorodyne, and one ounce of infusion of gentian, twice a day.

31st.—Pulse 92. Cough very troublesome last night, and after a paroxysm free hæmorrhage came on from carotid wound at 9 P.M. Applied lint soaked in tincture of iron, and strapping, and gave a dose of solution of morphia. This morning lies in a sleepy state. No more hæmorrhage; tumour pulsating forcibly; marked œdema of left hand; some œdema of feet.

Nov. 1st.—Pulse 95. Hæmorrhage again last night after a bad fit of coughing.

2nd.—Pulse 96. No hæmorrhage.

3rd.—Pulse 96. Coughs up a tenacious mucus.

4th.—Pulse 88; impulse feeble.

5th.—Pulse 86. Hæmorrhage at 5 o'clock this morning.

7th.—Pulse feeble. No particular pain in chest. Has had a little œdema of right eyelid for the last two or three days, and to-day the cornea looks cloudy, and is apparently perishing.

9th.—Cornea has given way; vitreous and lens escaped; eye collapsed. Face a little drawn to left; swallows without much difficulty.

10th.—Hæmorrhage again at 8.30 when in the act of smoking; arrested by the same means as before. Has no difficulty of breathing if he turns his head to the right, but it comes on if he turns it to the left.

11th.—Pulse weak and intermitting; complains of no pain, but, putting his hands together, says "his breath is like that."

12th.—Died comatose at 10 o'clock this morning.

Necropsy, six hours after death.—Body thin, but not emaciated. Base of neck above the collar-bones bulging, a plug of coagulum presenting at lower part of carotid wound. In removing the sternum and sternal end of clavicle careful dissection was needed to avoid tearing the parts immediately beneath. The ascending aorta was generally dilated, and arising from it was a semi-solid tumour, formed by the arteria innominata, the size of a small orange. Pericardium filled with fluid. Upper part of right lung symptoms of recent pleurisy. The right subclavian artery was obliterated, and adherent at ligatured part to the first rib. The aneurism had given way just below the ligature of the carotid; the pneumogastric nerve was flattened out on the aneurism. Adhesion of descending aorta to spine, tearing at one point, where a distinct little aneurism, size of a walnut, had corroded the bodies of the tenth and eleventh vertebræ. Lungs were adherent in parts from recent pleurisy, and filled with frothy mucus, but not consolidated. Dura mater adherent in several parts to hemispheres; pia mater opalescent, and evidences of chronic irritation as seen in hard drinkers; excess of fluid at base of brain. Brain-substance pale and soft. The "posterior communicans" artery on right side obliterated, or rather reduced to a fine fibrous thread. Liver very contracted, with marks of old inflammation on its capsule.

The man survived the operation sixty-five days. I think that, had it not been for his imprudence in exposing himself to the cold night air and setting up the acute attack of pleurisy, he would have survived longer; the paroxysm of cough put more strain on the circulation than the weakened artery could bear. But that he would have lived much longer is very improbable, as there was a spot on the posterior aspect of the aneurism which was as thin as a kid glove, and which would have soon given way. I think the man's life was prolonged by the operation—a questionable benefit. I have no doubt he was spared much suffering, both by the operation and by the use of aconite; for had it been left to nature, the tension and erosion of unyielding tissues would have caused constant severe pain, whereas from the time of the ligature of the arteries the pain was diminished in a marked degree; and the end was certainly a euthanasia in comparison with that which I have seen in other cases of aneurism.

In a younger subject, and with as distinct a diagnosis of innominate aneurism, I should not refuse a similar operation; but the diagnosis as to whether the arterial change is limited to the innominate is difficult—that it should be so limited is improbable.

As far as my experience goes, I believe that chronic alcoholism and syphilis are the two most important causes in bringing about that condition of artery which results in aneurism.

ALCOHOL AS A GENERANT OF THERMO-ELECTRIC CURRENTS IN THE SYSTEM: ONE OF ITS MODES OF ACTION.

By JOHN MULVANY, STAFF-SURG. R.N.

SOME years ago, when the application of ice to the spine became popular, I performed a series of experiments for the purpose of ascertaining its mode of action. Commencing on the lower animals, and studying its influence on the bloodvessels of the brain, with the sympathetics integer or interrupted in their continuity, I soon became cognisant of the initiation of thermo-electric currents by thermal disturbance.

Searching for manifestations of electricity in man from a like source, I was obliged to experiment on an individual whose appreciation of a glass of grog made him willingly submit to the discomforts of the spine-bags; and in him I accidently discovered that the deviation of the magnetic needle employed was always augmented by an ethylic potation. The same effects were also visible in other subjects, but my galvanometer was too imperfect to attach much importance to the phenomenon. When, however, four years later (1871), chance gave me access to a flash galvanometer belonging to the Indian Government, an instrument of the most marvellous delicacy, the circumstance recurred to my mind, and, having obtained the assistance of one of the ablest operators in the Indo-European telegraphy and a medical gentleman in the same department, I proceeded to investigate it in a manner the least compatible with error.

The existence or non-existence of electrical currents in the body first engaged our attention.

We observed that the formation of circuits was always attended by a manifestation of electricity; that this was not constant in point of force, but began soon after reaching its maximum to oscillate, the flash passing and repassing zero until it reached a point at which it remained stationary; further, that the maximum and stationary forces, though pretty constant in the same circuits in the same individual at different times, exhibited inequalities in strength in closely adjacent circuits and in different subjects, which could not be accounted for by extent of circuit, resisting media, or action on the poles, chemical or calorific. The dissimilarity in this respect witnessed in natives of India and Europeans was exceedingly curious and interesting, as will be seen by the subjoined specimen. In the respective circuits indicated the deflection to the right was as follows:—

	From tip of tongue to sinciput.		From tip of tongue to nape.
In a Mussulman	3°	......	8°
In a Goanese	2°	......	5°
In an Irishman	10°	......	22°
In a Scotchman	22°	......	25

Having accumulated a sufficiency of data to enable us to form an estimate of the influence of posture, rapidity of the circulation, direction of the head, ascertained the force of the earth-currents, and calculated the reducing currents from above downwards, we proceeded to try the effects of alcohol.

Mr. J——, aged thirty-three, being seated in a chair, a circuit was formed between the tip of the tongue and the nape of his neck. When sufficient time was allowed to the flash to cease oscillating and attain its stationary point of deflection, he took one ounce of brandy in three ounces of water. The electrodes were maintained *in situ* during deglutition, as well as throughout the entire observation, to guard against the error which might arise from the breaking and reforming of the circuit, and the flash was carefully watched. Before grog the galvanometer showed 15° right deflection, and during the twelve minutes immediately following, it did not register any appreciable alteration; but when thirteen minutes had elapsed, it suddenly showed a considerable access of electricity, which, with its subsequent behaviour, will be seen recorded in the following table:—

Before grog ... ... 15° right deflection.

	Minutes.		°	Minutes.		°	Minutes.		°
After grog.	12	...	15	25	...	32	35	...	23
	13	...	26	30	...	25	36	...	23
	14	...	40	31	...	23	37	...	23
	15	...	25	32	...	23	38	...	23
	16	...	20	33	...	23	39	...	23
	19	...	25	34	...	23	40	...	23
	20	...	22						

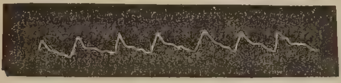
At this period heat and fatigue obliged us to bring the experiment to a close. So closely did the results observed in others resemble those just detailed that it will suffice to briefly allude to two of them.

In Dr. G——, aged twenty-eight, strong and healthy, an ounce of brandy raised the deflection from 14° to 60°; and at the end of half an hour it remained stationary at 45°. In a Goanese servant it augmented the stationary deflection 10°—i.e., from 2° to 12°. The maintenance of a strong current for such a long time as thirty to forty minutes removed any suspicion of its being excited by chemical action on the poles; whilst its force served to eliminate terrestrial currents from amongst its sources (these were never higher than 3°); and as muscular quietude was as far as possible ensured and emotional excitation entirely out of the question, especially in the Goanese, an utterly unimpassioned subject, there is, I think, but one interpretation applicable to these experiments—viz., that the electrical currents indicated by the galvanometer over and above the stationary forces were clearly owing to alcoholic action. Their connexion is one of cause and effect. The phenomenon was, in fact, but a simple transmutation of force—a conversion of heat into electricity. And as the dynamics of organised as well as of inorganic bodies are precisely similar, and their forces equally modifications of motion; moreover, as heat and electricity are radically but expressions of different conditions of the same all-pervading ether, and herein so intimately allied in nature that they are mutually convertible, such a transformation can be conceived to take place within the body as readily as without it, and be equally appreciable under suitable conditions. That these conditions obtain in the system may be inferred from the analogy which a circuit of dissimilar nerves bears to one of dissimilar metals, and from the fact of the pupil dilating and contracting by the currents derived from the application of cold and heat to the neck when the radiating fibres of the iris have been paralysed by section of the sympathetic, and from other considerations that may be learned from the following experiment, which, in conjunction with Drs. M'Callum and Farrel, of Dunnville, Ontario, I performed in 1867. Having exposed a portion of the right hemisphere of a rabbit, and observed the effects of heat and cold applied to the spine, I rapidly performed section of the corresponding sympathetic about an inch and a half above the lower cervical ganglion. The pupil contracted to the size of a pin's point, the plica semilunaris passed over a great portion of the eye, and the brain protruded through the opening to a considerable size. Ice was now applied to the shaven neck. The protruded brain passed inwards with a jerk, the pupil dilated, and the semilunar fold was visibly retracted. Hot water having been substituted for the ice, all the former conditions were restored. We now passed a magneto-electric current through the cerebral portion of the divided nerve to the brain, and observed the brain recede, the pupil dilate, and the plica shrink in a manner precisely similar to that occasioned by the cold. The rapidity with which the radiating fibres of the iris, though paralysed by section of their motor nerve, responded to the application of heat and cold, together with the fact of the sympathetic having been cut above the cilio-spinal region, clearly indicated that their muscular element was not affected primarily by cold in its simple physical capacity as a negation of heat, nor secondarily through the circulation by vaso-motor action. Moving the ice downwards, the pupil ceased to be affected when applied below the sixth cervical vertebra; the involuntary muscular tissue of the iris, the vital magnetometer, showed by its non-action that the current took another direction, passing through a circuit below what may be called the cerebral one. *Ex uno disce omnes.* When, therefore, in the vital as well as in the metallic circuit, inequalities of temperature, local accessions or deperdition of heat, disturb that mutual harmonic ratio between the ultimate elements and their interpenetrating ether which conditionates electric equilibrium, currents are excited which in the one case, as in the other, will have a definite direction flowing from the part most elevated in temperature. When alcohol is taken, the principal site of disturbance will be in the encephalic centres, and its source the heat liberated by the condensation which ensues when it osmoses into the brain-cells; for as alcohol, in virtue of that marked electivity it exhibits for nerve-tissue, especially for the brain, passes from the circulation to be stored up in that important organ to an extent equivalent to $\frac{1}{134}$ of the weight of the whole cerebral mass (Lallemand, Perrin, and Duroy), the watery element of the brain-cells is brought within the sphere of its chemical affinity, and as water enters into their composition in an inordinately high ratio—80 to 85 per cent.,—a considerable action will ensue, and condensation, with a liberation of heat, will be the physical resultants. As in the apparatus of Marcus or Melloni, the heat set free will be transformed into electricity, which will flow from the site of thermal exaggeration—that is to say, outwards, or in the direction it would take if a parallel condition were brought about by lowering the temperature at the opposite point of the circuit, which may easily be done by the application of cold to the spine. This is a powerful thermo-electrical excitant—so much so that, as will be seen by the following exemplum, it is capable of reversing the character and direction of the current when this happens to be negative. Bared to the waist, and the stationary forces of sundry currents noted by the superintendent of telegraphs, Dr. G—— threw a fine spray of ether on my spine. The following results were noted:—In a circuit from tip of the tongue to the sinciput, before the application of ether, the deflection was 10° left; after, 25° right. From tip of tongue to nape of the neck, before the application of ether, the deflection was 22° left; after, 20° right. From tongue to sixth cervical vertebra, before the application of ether, the deflection was 20° left; after, 13° right. Thus in this instance it changed the character as well as the deflection of the current, causing the flash to travel down to zero on the one scale, and attain a permanent altitude on the other. In persons whose primary deflection was right, the rise was instantaneous; in no case did the accession of force fall less than 10°.

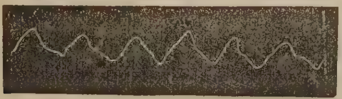
The application of hot water reversed the currents, and caused left deflection, showing beyond a doubt that, however else local applications of heat and cold may act, they undoubtedly give rise to thermo-electric currents. But marked as were these effects of heat and cold, those of alcohol were not less so. An equally significant manifestation of thermo-electricity ensued on taking a glass of brandy-and-water as that already witnessed when ether had been used. Negative deflection was again changed into positive, the character of the current was reversed, and the stationary force at the end of half an hour showed the passage of a positive current of 10° force.

It is, I think, in this action of alcohol that many of its beneficial effects as a medicine are to be sought. The currents generated in consequence of its action on the watery constituent of the brain-cells go to supplement enfeebled nerve-power, to strengthen the action of the heart and equalise the circulation. This is well illustrated by the following sphygmographic tracings taken on myself when suffering from debility from heat and a recent sunstroke. No. 1 represents a pulse of 110, with low arterial tension, and heart weak and prone to palpitate on slight exertion. No. 2 depicts the same pulse reduced to 98 two hours after 4 oz. of port wine had been taken, and shows the arterial tension raised as expressed by the rounding of the apicial angle and leaning upstroke, and the heart strengthened, as shown by the greater height to which the lever was elevated at the moment that the freedom of transmission through the capillaries was lessened. Had it acted simply as a cardiac stimulant, leaving the lax capillaries unaffected, or had it in the smallest degree augmented the then existing relaxation of these vessels, the heart's action would have been accelerated; or had it, on the other hand, simply confined its action to contracting the capillaries and raising arterial tension, the heart would not show an immediate accession of force as it did. But it acted on the entire circulation, contracting the peripheral capillaries, and thereby diverting the blood from the centrifugal direction impressed on it by the circumambient heat and humidity; it threw a fuller stream inwards, and rendered more active the circulation through the chylopoietic viscera and the internal organs, and thus brought about those conditions which are favourable in a high degree to nutrition and hæmatosis.

No. 1. Before wine.



No. 2. Two hours after wine.



Hence, though alcohol cannot be considered to act in the ordinary manner of foods, and does not contain a particle of those nitrogenous elements which on assimilation go to repair the loss sustained through disintegration, its *rôle*, if judged by its results when given under appropriate conditions, is certainly that of a food.

In order that its administration be opportune there should be clear evidence of derangement of function springing from enfeeblement of the organic system of nerves, for then not only will the adventitious aid given by the thermo-electric currents it excites be profitably appropriated to the restoration of healthy function, but the brain-cells, owing to the condition of languor and hebetude which impaired nutrition entails on them, will admit a portion of their water to be abstracted with impunity; indeed, it is not difficult to imagine that such an abstraction, if temporary and slight, will not only be innocuous, but positively advantageous, by the brisker action, osmotic and exosmotic, incited by the presence of alcohol for the purpose of effecting its removal, and the restoration of the abstracted water giving a fillip to nutrition; whereas in health, when function, nutrition, and blood and nerve influence are harmonised by structural integrity, such an abstraction must interfere with their normal working, and the electric currents generated under these circumstances, being superfluous, will fail to compensate for the interference with the steady elaboration of nerve-power. Should the accession of force through electrical agency be the exact counterpoise of that lost by the nervous channel, the detriment will be transitory; but should the dose of alcohol be large, not only will danger arise in proportion to the extent to which the cells become exhausted of their water, but also to the extent that their vital functions are replaced by physical ones; for, judging from analogy, thermo-electric currents set in motion in the brain, if too powerful, will overpower and suspend its functions, just as the too powerful stimulus of exciting passions acting on its cineritious substance would do, did not an hysterical paroxysm, spasm, or convulsion act as a safety-valve; or as the cognate electricity developed by a battery, if passed through the vagi in sufficient strength, stops the heart's action, or suspends the play of the diaphragm acting on and through the phrenic.

The similarity of the galvanometric effects produced by the internal use of alcohol and the external use of cold is strongly suggestive of its applicability in cases where cold shower baths would be serviceable, but are not attainable; such as in great and moist heats. And here its moderate use is not only justified by theory, but the theory is verified by the results. During a long sojourn in the Indian Ocean and the Gulf of Persia I had ample opportunities of observing that those who became teetotalers lost in weight, *élan*, and muscle; the gastrocnemius visibly diminished in bulk; and fatigue became so easily induced that I found these men philosophising on the inutility of tiring themselves by scrambling up the mountains of Seychelles, instead of dashing at them *en étourdi* as their comrades did. Periodical weighings of some of the officers of my ship and myself gave the most indubitable testimony that the use of alcohol in a mean temperature of 85° tends to keep up the weight of the body. In one instance a reduction of seven pounds took place in fourteen days in an officer who only exchanged habitual temperance for teetotalism. The falling away in strength he experienced at the same time; and this, its tangible equivalent in weight, somewhat alarmed him, and caused him to resume his former habits. The recuperation of weight was as rapid as had been its loss. In temperatures of 85° and upwards, with an absence of wind, or at most but gentle zephyrs being felt, and with an atmosphere from 75 to 90 per cent. saturated with humidity, the elastic pressure of the atmospheric vapour often equivalent to 1′ and upwards of mercury, evaporation is so greatly impeded that perspiration pours from the skin in such a copious stream that it constitutes a serious source of enfeeblement. On one occasion I calculated, by placing a piece of blotting paper under a glass on the chest of a messmate, seminude, under a windsail, temperature 93°, that he was at the time sweating at the rate of 1 gallon and 1⅛ gill for the twenty-four hours. Such a drain as this from the blood necessarily interferes with nutrition, and reduces the weight of the body. And experience has taught me that in circumstances such as these—namely, when rapid loss of weight is an attendant on copious perspirations—alcohol may be safely used in moderation. As it is under these conditions that I met with a permanent left deflection of the galvonometer —conditions benefited by alcohol,—I would be inclined to regard the presence of this phenomenon as an index of its suitability. Valuable information of similar purport may be gained by using the stethoscope and sphygmograph; for the circulatory system and the organic system of nerves are so interrelated that the condition of the latter may, to a great extent, be realised from the working of the heart and small arteries.

Southsea.

AN IMPROVED METHOD OF TREATING CERTAIN CASES OF CATARACT REQUIRING EXTRACTION.

By JAMES VOSE SOLOMON, F.R.C.S.,
SURGEON TO THE BIRMINGHAM EYE HOSPITAL;
PROFESSOR OF OPHTHALMIC SURGERY IN QUEEN'S COLLEGE.

IN some ophthalmic works which discuss the cure of senile cataract, the presence of a deep-set eye is given as a reason for the selection of depression or reclination in preference to the operation of extraction. I imagine no surgeon who has had experience in such cases will deny that a deep-set eye occasions some embarrassment in the making of the corneal section with a Graefe's or Beer's knife, especially where anæsthetics are not employed.

In a case recently operated upon at the Birmingham Eye Hospital, I improvised a simple and effective method of overcoming the difficulty under consideration by making with a pair of sharp scissors a perpendicular incision through the substance of the lower lid of about three-eighths of an inch in length and one-sixth of an inch from the commissure. Steady continuous pressure by means of a small sponge restrained the bleeding within innocent limits. The front of the eye having been now made easy of access to the knife, the section of the cornea was completed without difficulty, and the lens safely delivered without accident. No anæsthetic was employed. The lid was not sutured, but dressed with cerate instead of dry rag, and two turns of a narrow domett roller. The patient, a collier of sixty-eight years, recovered without a single painful or unfavourable symptom, and was discharged cured on the fourteenth day of the operation, with a clear black pupil, good vision, and perfect cicatrisation of the tarsal cartilage.

The above plan should have preference to any that interferes traumatically with the condition of the commissure, from the impossibility of its inducing abnormal contraction of the palpebral aperture or inversion of the lid (entropion) —accidents of no mean importance.

The operation of *reclination* has fallen into undeserved neglect, and, as a consequence, eyes are destroyed which would have had a good chance of vision if it had been selected for performance instead of extraction. A resort to it would be advisable where there is extensive fatty degeneration of the cornea and other tissues, and in subjects in whom the arteries have become seriously spoilt by atheroma, also in those who are affected with tertiary syphilis of old date. In the last two pathological conditions, intra-ocular hæmorrhage is the complication to be dreaded after the removal of the lens, or even upon the mere evacuation of the aqueous humour (no hypothetical case); in the first, death of the corneal flap within eighteen hours of the performance of the extraction is not uncommon.

Birmingham.

IN London last week 1471 deaths were registered, including 35 from measles, 96 from scarlet fever, 11 from diphtheria, 58 from whooping-cough, 22 from different forms of fever, and 138 from diarrhœa. No death from small-pox was reported. It is satisfactory to observe that the fatality from diarrhœa is declining, but the same cannot be said of scarlet fever. Two fatal cases of diphtheria occurred in St. Bartholomew's Hospital. The death-rates of some of the continental cities have lately been very high, Berlin, as usual, leading the list with a mortality of 48 per 1000 annually.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum, tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Prooemium.

ST. BARTHOLOMEW'S HOSPITAL.

TWO CASES OF RHEUMATISM; RECOVERY.

(Under the care of Dr. SOUTHEY.)

FOR the notes of the following cases and the accompanying remarks we are indebted to Mr. George Hastings, house-physician.

Two patients, lately lying side by side in Faith ward, suffering from rheumatism, presented such marked similarity in history and symptoms, both of which were anomalous, as to raise the suspicion that they were not ordinary cases of rheumatism, and were therefore of more than usual interest.

J. C——, aged forty-three, a married woman, was admitted on the 26th of April, giving this account of herself:—Eight days ago, after a violent domestic quarrel, her husband turned her out of the house, and she passed the whole night on the door-step. On her readmission in the morning, and after she had got comparatively warm and comfortable, fits of shivering came on at intervals. The next day the right wrist became almost suddenly swelled and very painful. This continued to be the great source of suffering until the time of admission. A copious vaginal discharge, accompanied by pain on passing her water, had been present for three weeks. It may here be mentioned that the husband is at this time suffering from a severe attack of gonorrhœa, and is being now attended by a medical man in the neighbourhood.

On admission, eight days after the onset of the pain and swelling of the wrist, she was fairly nourished, but anæmic; complexion fair. Right wrist-joint red, excessively tender, and much swollen. General hyperæsthesia over the whole of the body, but no tenderness or swelling of any other joints. There was an abundant purulent discharge from the vagina, with pain and scalding on micturition. Tongue coated with thick yellow fur; bowels confined. Complained of great thirst, with loss of appetite, and continued sleeplessness on account of pain in the wrist. No cardiac complication or history of previous rheumatism. Temperature 100° F.; pulse 90, feeble. The urine on examination was found to contain a small quantity of pus. The patient was ordered quinine, with iodide of potassium; a local application of chloroform and belladonna for the wrist, and an astringent lotion to the vagina.

The note of May 19th says: "Her general condition has improved, but the pain and swelling of the wrist-joint has not yielded to the treatment, and continues in a chronically painful and stiffened condition, in spite of varied local applications. Some slight pain is complained of in the right shoulder on extension of the arm. The vaginal discharge, however, has ceased."

June 3rd.—The patient has steadily improved since last note, although no especial alteration in treatment has been made. Was discharged at her own request, with no pain, but some stiffness of wrist, and very much improved in health.

E. P——, aged thirty-one, single, general servant, was admitted on April 15th into Faith ward with the following history:—Nine days before admission she had several long shivering fits, and on the following morning found that the left wrist was swelled and very painful. At the same time some slight pains were present in the ankles and calves of legs. She had had a thick vaginal discharge and scalding pain on micturition for three weeks.

On admission, she was a well-nourished, fair woman. On examination, the left wrist-joint was found much swollen, hot, very tender, and covered with a deep red flush, extending on to dorsum of hand. No tenderness or swelling of other joints. Heart-sounds clear and natural. No previous attack. Temperature 99·4° F.; pulse 76, fair volume.

For three days after admission she had retention of urine, and was only able to void it in a hot bath once a day, the urination being attended with very great pain and scalding.

The urine, when examined a few days later, was found to contain about one-sixth pus.

The treatment ordered was similar to that of the other case.

By May 20th the intensity of the pain had passed away, but the hand and wrist-joint remained stiff and useless; great pain was also produced on any attempt at movement, no relief being obtained from fomentations, shampooing, or blisters. Discharge from vagina almost cured.

May 28th.—Has a slight attack of facial erysipelas, with moderate pyrexial symptoms, lasting five days.

From that time the stiffness and uselessness of wrist have rapidly disappeared without any local treatment.

Patient discharged well.

The points of analogy in these two cases are certainly clear:—The sudden invasion with rigors, so rapidly followed by severe local inflammation of only one joint, and that joint the wrist in each case. The presence of vaginal discharge of three weeks' duration, almost positively gonorrhœal. The absence of any complication or metastasis, of high or vacillating temperature. The more than usual chronicity and resistance of treatment, both local and constitutional, each being first attacks, and the trifling but curious coincidence of their accidental position side by side.

On careful examination of the notes of 202 cases of acute rheumatism in the female, treated in St. Bartholomew's Hospital, in not one is the presence of any vaginal discharge coincident with rheumatic inflammation of joints mentioned, or any history of the whole stress of the inflammation from beginning to end falling upon one joint alone.

MILLBANK PRISON HOSPITAL.

PERSISTENT HEADACHE; PARTIAL APHASIA; DEATH BY COMA.

THE following case is reported by Mr. Henry Brietzcke, F.R.C.S., assistant-surgeon, with remarks by Mr. R. M. Gover, medical officer.

The discussions which have taken place with reference to the researches of Drs. Hitzig and Ferrier, and the remarks recently made on the subject of intracranial disease, impart a special interest to the following case, which to some extent illustrates several points which have been of late brought prominently forward.

T. F——, aged fifty-two, a prisoner under sentence of seven years' penal servitude, was admitted into hospital January 12th, 1875, complaining of pain in the head on the left side, which, he stated, commenced suddenly five weeks before. On examination, there was a distressed look, and a tendency to shed tears. The man was well nourished, of a short and stout build, slept fairly well, and took his food well. When describing the pain he said it was severe, and always in the same spot, and that the skin was sensitive in that region. At this period there were no other symptoms.

On the 7th of April he stated that his sight was leaving him, also his hearing, and that he wished the "Lord would take him." The voice was muffled as if he was deaf, but he could hear when spoken to in a low tone.

With the ophthalmoscope the optic disc on the right side appeared very white, with an irregular margin and slight deposit of pigment on one side, and the retinal veins were large. In the left eye the retinal veins were much larger, but the disc was not irregular. Iodide of potassium was prescribed.

On May 28th he was seized with peculiar shudderings, occurring at intervals of about ten minutes, and with cramps in the legs, partial anæsthesia of face, neck, and upper extremities, but no loss of motor power. At this time slight ptosis of the left eyelid was noticed. A day or two after this the ptosis was more marked and the shudderings appeared to be started by a whiff of cold air or a scratch with a pen. The tongue was foul, and he vomited frequently. On the 2nd of June his condition was as follows: Slight drooping of left eyelid, but the other muscles of the eye supplied by the third nerve act well; pupils natural; no loss of sensation in the face, but the expression is different. Patient complains of numbness in the right arm; when he tries to walk he staggers, especially when the eyes are shut, but he does not fall or drag a leg; tongue foul; vomiting not entirely subsided.

June 3rd.—To-day he is in tears, and says he cannot speak well; he talks sensibly, but hesitates, and has some difficulty in selecting certain words. The shape of the mouth is slightly altered, especially when he talks; tongue furred; pulse quiet and regular; temperature 100·6° F.; second sound of heart prolonged; urine loaded with lithates; no albumen; cerebral macula moderately well marked.—*Ophthalmoscopic examination*—Left eye: Fundus red and cloudy, completely obscuring optic disc and vessels.—Right eye: Dark patch on outer and upper aspect of disc, extending nearly half round circumference. There is a hesitation in speech, and he takes some time to express himself, but he does not use the wrong word, and remembers his age, date of conviction, &c.

4th.—Complains very much of his right arm; it is not paralysed, but he continually rubs it, as if it were painful. He cannot express himself as he wishes, apparently forgetting the words "arm," "pain," "shoulder," but uses the first syllable of the latter, tries hard, and says "Oh dear!"

From this time delirium at intervals supervened, the temperature rose to 102° F. daily, and coma gradually set in, with subsultus and involuntary evacuations, and death took place on the 10th.

Necropsy, twenty hours after death.—The body was well nourished. Head: Veins of scalp full; vessels on surface of hemispheres full; a small quantity of yellowish serous fluid beneath arachnoid on surface of both hemispheres. On removing the brain, the dura mater covering the posterior part of the anterior fossa of the base of the skull on the left side—viz., the upper surface and posterior border of the lesser wing of the sphenoid—stripped off easily, was thickened and evidently diseased, and the part of bone described was roughened and bare, the anterior clinoid process was denuded, and felt sharp and irregular. On examining the base of the brain, the divided end of the internal carotid artery on the left side was gaping, its walls thickened, and involved with the middle cerebral artery in a dense and irregular membrane, which consisted of the dura mater and arachnoid adherent and incorporated. This thickened part corresponded in point of position with the bare and rough bone. The divided end of the carotid artery on the opposite side was collapsed and natural. The fissure of Sylvius and island of Reil were normal on both sides. The left middle cerebral artery ran through the thickened dura mater and arachnoid, but it was quite pervious, and, on slitting it up and examining with the microscope, its coats were normal, and there was no atheroma. The third nerve on the left side was involved in the thickened dura mater, and passed through it, but was not in any visible degree atrophied; the left sides of the pons Varolii and medulla oblongata were somewhat softer in consistence than the right, and this change extended to the fifth and sixth nerves, as well as to the eighth and ninth at their superficial origin. The softening, though slight, was clearly made out; there was some fluid in the lateral ventricles, but this was not excessive in quantity. The convolutions, corpus striatum, thalamus opticus, and other centres, were quite healthy in appearance. The lungs were engorged, small scattered deposit of tubercle, with pleuritic adhesions. The pericardium was closely and firmly adherent, and could not be separated without tearing the cardiac tissue, and the lymph was evidently of old formation; muscular tissue of left ventricle thickened, but firm in consistence and ruddy in appearance; valves healthy. Other organs healthy.

Remarks.—The first symptom of decided importance, as indicative of intracranial disease, was the very severe unilateral headache, with the significant accompaniment of slight ptosis on the same side. The character and severity of the headache aptly illustrate the remarks recently made by Dr. Moxon on this subject, and it is important to observe that this was the only symptom which was well marked during the earlier history of the case. The absence of other symptoms may without doubt be attributed not only to the limited extent, but to the site of the morbid processes then in operation, removed, as it was, from the great motor centres. One of the most interesting features in the case was the stationary character of the symptoms, and the absence of any indications of progressive organic change up to within a few days of death; and it may be well to draw attention to the complete absence of paralysis, with the exception of the partial ptosis, up to the time at which coma set in. The aphasia was due, not to any difficulty in the mechanical act of articulation, or in the origination of ideas, but it resulted from an inability to seize upon or arrange the words corresponding with the thoughts he evidently wished to express. It will be noted that the left middle cerebral artery, though involved in the thickened dura mater, was pervious. There was no apparent lesion of Broca's convolutions, or of the corpus striatum, or of any of the great nuclei in the neighbourhood. The alteration in the consistence of the pons and medulla, which was confined to the left side, was probably acute, and unconnected with any vascular lesion or obstruction. It is probable that the disease was specific, that it commenced in the dura mater, and extended to the subjacent bone, producing caries. The lesion was situated in close proximity to the fissure of Sylvius, and the part of the brain about which so much has been written with regard to the faculty of speech, but although it was sufficient to produce a temporary aphasia, it had not extended into the cerebral substance or reached the motor centres, and this may account for the absence of paralysis. The third nerve was involved either in the outer wall of the cavernous sinus, or, more probably, in the sphenoidal fissure, as the branch which supplies the levator palpebræ was principally affected. The ophthalmoscopic appearances were very interesting; possibly pressure on the third nerve produced alteration in the nutrition of the eye through the lenticular ganglion, and thus caused an appearance as of a cloudy vitreous. The adherent pericardium was not diagnosed during life; the only note made was to the effect that the second sound of the heart was prolonged.

EDINBURGH ROYAL INFIRMARY.

SURGICAL CASES.

(Under the care of Mr. Joseph Bell.)

For the notes of the following interesting cases we are indebted to Mr. Holland J. Cotton, house-surgeon.

Case of Compound Comminuted Fracture of Lower Jaw; threatened Spinal Meningitis; Recovery.—Harriet L——, aged seventeen, a servant-girl of weak mind, was admitted on the 28th November, 1874, suffering from a compound comminuted fracture of the lower jaw on the left side, a lacerated wound over the patella, and a bruise over the lumbar region of the spine. The patient, in a state of temporary frenzy, had thrown herself from a window four storeys high, in one of the best squares of the city, but her fall was happily broken by coming in contact with the sloping roof of an out-house. Mr. Bell, who was sent for at once, found a lacerated wound, fully three inches long, over the left horizontal ramus of the jaw, which itself was shattered into several fragments and protruding from the wound. The cavity of the mouth was opened into, and several teeth were broken and hanging loose. Having removed all loose fragments of jaw, but with as little of the periosteum as possible, Mr. Bell brought the upper and lower fragments together by boring the bone and passing stout silver wire through it. The bleeding was easily stopped, although the facial artery was completely torn across. A portion of dental nerve too, which was lying exposed, had to be removed. The wound was then sewn up, a drainage tube being passed right through into the mouth.

For the next three nights the patient was in a most critical condition, suffering from convulsive attacks of the muscles of the face and limbs, and presenting most of the symptoms of spinal meningitis. At the suggestion of one of the physicians to the hospital, forty grains of the bromide of potassium were given five or six times in the twenty-four hours, with an occasional dose of chloral at night, instead of the fifteen-grain doses of bromide of potassium and chloral thrice a day which she had previously taken. This in a few hours had the desired effect of subduing the constant twitching movements and removing the sleeplessness. The patient having thus been brought fully under the influence of the drug, the large doses were discontinued, and only a moderate dose administered whenever twitching of the muscles or great restlessness occurred. The wound meanwhile progressed favourably enough, being daily washed with a weak lotion by means of the tube which communicated with the mouth. There was much swelling of that side of the cheek, and there was a copious fetid discharge. The wound over the patella healed slowly, but was quite superficial, whilst the bruise over the spine was followed by no discolouration from ecchymosis. For days after, convulsive movements, however, could at once be brought on by firm pressure over one spot along the spine; and though the patient was eminently hysterical, yet these movements were evidently involuntary.

The after-progress of the case was slow, the fragments of jaw still crepitating, and occasionally causing considerable pain. A sinus remained; but at length (nearly two months after the accident) the two pieces of silver wire, which had held the fragments together, along with several spicula of dead bone, were expelled from the external orifice. By this time the jaw was consolidating rapidly, much new bone being thrown out, and little inconvenience being experienced therefrom. In another month the sinus had almost completely healed, and the patient ceased to attend the hospital, her jaw being firmly united, and her face wonderfully little distorted.

Case of Acute Necrosis of the Ulna; Removal of the entire Shaft; rapid Reproduction; Recovery.—Marion M——, aged eight, was admitted on the 31st of December, 1874, suffering from acute necrosis of the right ulna, and an incipient lumbar abscess. On the eighth day of the same month she had complained of shivering and headache, then of pain in her right forearm; and on the third day a red line was noticed stretching up the inner side of the limb, with swelling as far as the elbow. A doctor was called in, and he, after a week's attendance, incised the arm in two places and evacuated some pus; but finding that the patient was daily getting worse, and that an abscess was threatening to form over the right dorsum ilii, he sent her to the infirmary.

On admission the child was very weak, and looked excessively ill, complaining of much pain in the arm and back. On Jan. 2nd Mr. Bell removed the whole shaft of the ulna, which was necrosed, leaving the periosteum entire as far as possible, and at the same time he evacuated some serum from the lumbar swelling by means of a trocar. The patient improved rapidly after the operation, regaining her appetite, and looking quite a different child. The lumbar swelling disappeared, whilst in the arm much new bone was thrown out, and the wound granulated healthily.

On Jan. 30th she became an out-patient, and came occasionally to have her arm dressed. The whole shaft of the ulna had been reproduced, and the movements of pronation and supination were practised daily. For some weeks after a sinus remained, through which occasionally spicula of bone escaped, but this finally healed up; and the patient was dismissed with an arm capable of perfect movements, the ulna being slightly thicker than that of the other arm. Of the lumbar swelling nothing remained but a thickening of the crest of the dorsum ilii.

Reviews and Notices of Books.

Traité de Thérapeutique Médicale, ou Guide pour l'Application des Principaux Modes de Médication à l'Indication Thérapeutique. Par le Dr. A. Ferrand, Médecin des Hôpitaux de Paris. Paris: Baillière.

The relations of therapeutics are twofold. Its province is to determine the application of remedial agents to diseased action. On the one hand, therefore, it has to consider the disease, and on the other the remedy. Its study may be approached from either side. It is commonly taught in conjunction with materia medica. This method has a certain convenience, but it is founded on a connexion which is not, perhaps, the most important of its relations. A separate monograph on the action and use of each drug necessitates a minute subdivision of the subject of therapeutics, and a disjointed and most unsystematic treatment of each part. It is upon this plan, however, that most treatises have been written, as, for instance, those of Pereira, Garrod, Gubler, Stillé, &c.; but the method has never satisfied the earnest therapeutist. The fragmentary and disjointed presentation of the subject, like a reflection from broken water, conveys a very imperfect idea of its scientific form; hence many attempts have been made to unite the scattered elements. Groups of remedies have been considered together, a common description of their action being given, and thus by describing together cognate subjects, and avoiding unnecessary repetition, better system has been secured. But it is evident that any discussion of therapeutics from the side of drugs must leave one half, and that the more important half, of the subject very imperfectly treated. What to administer under any given circumstances must always depend as much, or more, on the occasion as on the substance to be given. In each disease, in every variety of each, the needful remedial agent or the mode of its administration may vary, and it is in the due recognition of the significance of each indication for treatment that the more refined part of the science and art of therapeutics consists. It is this part which admits, we are told, of the most systematic treatment—which can be raised with most completeness to something like scientific dignity. This part of the subject is considered, it is true, in the systematic treatises on disease, but it is there subordinated to diagnosis and pathological anatomy, and is not discussed with that width of generalisation which its importance and capabilities deserve. To effect this is the object of Dr. Ferrand's treatise.

A little consideration will render it clear that the indications for treatment which different diseases afford are of so varied a character that any attempt at their generalisation must produce a system of considerable complexity. This is unquestionably the case in that which is unfolded in the work before us. The various "indications" for the treatment of disease may be grouped in three classes—those afforded by the nature of the malady, by its form, and by its local manifestation. These are termed respectively the "nosological," "physiological," and "anatomical" elements, all of which are presented by each case of disease submitted to treatment. As therapeutical indications these elements differ in value. The nosological element, the essential nature of the disease, is its effective, or rather its realised, cause. The physiological element is due to the reaction of the system against the malady, and determines the form of the disease. The local seat, secondary in point of time, which constitutes the third element, is of little value as an indication for treatment, since it is only a secondary fact in the constitution of the malady, and is of less significance as to the remedial agent to be chosen than as to the place and mode in which it should be used. The "nosological" element is intimately united to the idea of the specificity of disease, and furnishes an indication of greater value, as is shown by the instances in which there exists a specific remedy for a definite disease. But the rarity of the instances in which this is the case, and the purely empirical mode in which alone the indication can be utilised, narrow the part it can play in general therapeutics. The "physiological" element, that which determines the form of the disease, is the true ground of therapeutical indication. It is so termed because it rests on the physiological properties of the tissues, the reaction of which determines the form of the disease, but in its employment the effects of functional and of nutritive changes have to be carefully distinguished. We know the substances which, in a physiological condition, accelerate or retard the activity of this or that organic system; we know how far these substances preserve that property in the various derangements of these systems, to what extent they will excite or calm their elementary functions, and we can obtain, to a considerable extent, by the administration of this or that agent the effect we desire.

The practical application of these principles to various diseases involves of necessity the discussion at some length of many details in their pathology and symptoms. This constitutes indeed the main bulk of the volume before us. Various classes of maladies are successively considered—first, nervous affections, cerebral, spinal, and sympathetic; next, vascular affections; and, subsequently, troubles of secretion, of nutrition, alterations of the blood, inflammations, fevers, infectious diseases, constitutional affections, toxic states, and parasitic diseases. The several indications referring to each of these "elementary troubles" are successively studied: first, the signs which characterise each, the variations in intensity which it may offer, the consequences it may entail, its essential pathology, the various remedial agents which may influence it, and the more immediate indication in each case for their employment.

As an example of the system, the third part may be taken, the subject of which is the indication for treatment drawn from disturbances of the vascular system. The first chapter is devoted to the "indication furnished by vascular congestion." The elementary type of vascular congestion is first described—i. e., the general characters of the morbid process. Its "pathology" is then discussed, the nervous and other agents concerned being briefly spoken of. The second section is devoted to the "therapeutical indication," which is, in this case, the diminution of the afflux of blood in the distended vascular system; and the means by which this object may be attained are successively discussed—(1) hygienic methods, as food, posture, cold; (2) moderating remedies which may lessen the force of the blood and lower the temperature; (3) "contra-stimulant remedies," which, acting through the nervous system, seem to cause anæmia of organs; (4) stimulant treatment, when the congestion is associated with a sluggish circulation behind the affected part; (5) astringent treatment, local and general; (6) direct evacuant treatment, as by local depletion; (7) indirect evacuant treatment, as by purgation. An article follows on the "mediate indications" for treatment, furnished by the pathological state in which the congestion arose, as specific, diathetic, or degenerative disease. A final article on "application" contains sections on the various forms and seats of congestion, and their appropriate treatment: general congestion, and congestion of brain, spine, lungs, stomach and intestines, rectum, liver, spleen, kidneys, uterus, on congestions in fever, and on those secondary to diseases of the heart; and under each head the appropriate treatment is described. The remedies given as appropriate to renal congestion are to furnish the organs with the elements for ready secretion, by diluent drinks and milk, avoiding irritating substances, as alcohol, and giving salines and diuretics with great caution, favouring secretion from skin and intestine, and employing, when necessary, revulsive measures, as sinapisms, &c. In a similar manner, and at almost equal length, the phenomena of anæmia and hæmorrhage are discussed in their several relations. The other sections are treated in a similar manner.

The system thus sketched is elaborated in the work at detailed and cumbersome length, but with a completeness and a patience on which the author must be congratulated. The system itself is perhaps as thorough as the present state of our knowledge will permit. In working it out, however, the Materia Medica side of therapeutics has been necessarily altogether subordinated, so as to reduce the practical usefulness of the book far below its value as an exposition of the theory of therapeutics. Some portions of the subject, also, closely connected in theory, are separated here, but this is perhaps inevitable from its wide and varied relations.

The Surgeon's Pocket-book: being an Essay on the best Treatment of Wounded in War. By Surgeon-Major J. H. PORTER, late 97th Regiment, Assistant-Professor of Military Surgery, Army Medical School, Netley. London: Chas. Griffin and Co. 1875.

THE materials of this handbook formed the essay for which a prize was awarded by Her Majesty the Queen of Prussia and Empress of Germany in the year 1874, and they have been specially adapted for the public medical services.

Its conspicuous merit consists, in our opinion, in the skill displayed in the selection and arrangement of its information. It contains little that is absolutely new perhaps, but the information, which is of the most practical kind, has not been put together, as is too often the case, with little discrimination or judgment, but with an evidently honest intention of giving the military and naval surgeon an epitome of the latest and best views, and the most trustworthy methods, of treatment of the wounds and injuries incidental to warfare. To write a good book on a subject of this kind is really a far more difficult task than is generally imagined, for its author must not only have been an industrious and critical reader, but a sagacious and good observer of what the requirements of the army surgeon are under circumstances and in emergencies which try the practical ingenuity and judgment of a man in a way that they are never likely to be tried in civil practice, where there cannot be the same demand for promptitude and decision, where every appliance is at hand, and where the after-treatment of an operation can be carried on leisurely, and without the dangerous risks that have to be encountered in the field from overcrowding, insufficient food, hurried dressings, and frequent changes of locality. The author has not written a manual on surgery, of course, but limited himself to those subjects which concern the military and naval surgeon, including a variety of matters about which medical officers will find it very useful to have a ready guide in field practice. Without being too diffuse, the author has not erred on the side of being too dogmatic. He has given the different views and varieties of practice inculcated by different authorities where these are not agreed, leaving the reader to exercise his own judgment. He has drawn on the writings of German, French, Italian, and American surgeons, as well as those of this country, for the materials of his book, which is besides well illustrated, and altogether a very creditable and useful production.

Popular Natural Philosophy. Translated and Edited from Ganot's "Cours Elémentaire de Physique," by G. ATKINSON, Ph.D. Second Edition. London: Longmans. 1875.—We are glad to notice this little book, which will prove useful to a wide circle of readers and teachers, since it represents about the amount of knowledge required for the Matriculation examination of the London University. It is divided into eight books, treating respectively of the General Properties of Matter, Hydrostatics, Gases, Acoustics, Heat, Light, Magnetism, and Electricity. It is admirably illustrated, and throughout most clearly written. It ought to be in the hands of the higher classes of all our public schools, and if the principal facts it contains were early demonstrated by experiment to those about to become members of the profession we should have a far larger number of accurate observers, and much fewer loose theories than at present.

GLASGOW IN 1874.

THE annual report upon the "Vital, Social, and Economic Statistics of Glasgow for 1874" has recently been issued by Mr. W. W. Watson, the City Chamberlain, and contains invaluable materials for a careful study of the growth and sanitary condition of this important city. The population of Glasgow, which in 1801 was but 77,385, was estimated at 508,109 in the middle of 1874. Between 1811 and 1821 the increase of population was equal to 46 per cent., whereas in the last two decades, 1851–61 and 1861–71, it did not exceed 20 and 21 per cent. respectively. The marriage-rate in 1874 in Glasgow was equal to 19·7 per 1000, and corresponded with the rate in 1873; the birth-rate was 39·4 per 1000, a rate which considerably exceeded that which prevailed in any recent year, except 1872; the death-rate was also exceptionally high, and equal to 31·2 per 1000; excepting 1871, so high a death-rate has not prevailed in any year of the past decade. In referring to this excessive death-rate in Glasgow last year, it may be noticed that Mr. Watson has revived a now all but exploded false theory, when he says, "We must not lose sight of the fact that a very high birthrate, such as is exhibited above, leads of necessity to a heavy death-rate, from the very large proportion of the infantile deaths which occur in a dense manufacturing population." This fallacy, which was not long ago put forward by Dr. Letheby, was recently so conclusively exposed in a paper read before the Statistical Society that it is surprising to find one of its fellows reproduce it without any allusion to the controversy to which it gave rise. It has been proved beyond all doubt that in all populations in which high birthrates prevail the effect upon the death-rate of the large proportion of infants and young children is more than counterbalanced by the high proportion of young adults, among whom the rate of mortality is low, and by the small proportion of persons aged upwards of sixty years, who are liable to a death-rate nearly as high as are children under five years of age. Sanitary condition being equal, the deathrate in Glasgow ought to be lower than in the rural portions of Scotland, where the birth-rate falls below 30 per 1000. The explanation of the high rate of mortality in Glasgow in 1874 is, however, not very difficult to discover. The remarkable severity of the weather in the latter part of November and throughout December caused almost universally high death-rates. Glasgow suffered to an exceptional extent, even for a large town. During October 1274 deaths were registered, while the number rose to 2101 in December. The greatest sufferers were adults and elderly people; among children and young people under twenty years of age the deaths in December exceeded those in October by 26 per cent., between twenty and sixty years the increase was equal to 119 per cent., and among persons over sixty years to 208 per cent. As regards the causes of death in 1874, we find that bronchitis and pneumonia killed 3332 persons, against 2934 in 1873, and that the fatal cases of scarlet fever showed an increase of 1072. Much has undoubtedly been done in Glasgow in recent years to improve its sanitary condition, and it would be manifestly unfair to take the result of so exceptional a year as 1874 as evidence that no real improvement has taken place. Mr. Watson very properly calls attention to the marked decline in the deaths from typhus in recent years. In 1864 and 1865 the fatal cases in Glasgow were 1138 and 1117; the average annual deaths from this disease in the ten years ending 1874 declined to 479, and the numbers in 1873 and 1874 were but 79 and 114 respectively. When we observe, however, that the annual death-rate from the seven principal zymotic diseases was equal to 7·4 per 1000 of the population in Glasgow in 1874, whereas it was but 3·3 in London, and averaged 4·5 in eighteen of the largest English towns, the sanitary work that has still to be done in the largest Scotch town is but too painfully apparent. We shall anticipate with much interest the report of Dr. James B. Russell, the medical officer of health for Glasgow, upon the exceptional mortality during 1874.

THE LANCET.

LONDON: SATURDAY, JULY 31, 1875.

The case of George Blampied, lately tried at Maidstone, shows in clear contrast the medical and the legal views of the mental condition that involves irresponsibility. It is of the last importance that this contrast should be well understood. And although the law as laid down by the judge (Brett) on this occasion was, as might be expected, exactly what has been well known to the medical profession, it is desirable from time to time to reproduce it on every occasion of its practical application. We will therefore briefly state the case, quote the judge's exposition of the law, and offer some comments that appear to be called for in the interests of humanity and justice.

George Blampied, a man of middle age, was indicted for the murder of James Catt. They were both employed in the dockyard at Chatham. A few months before the deed in question they had had an altercation, but had since been on apparently good terms. On the 16th of April they were at work together on the same mast, about six feet from each other, and the prisoner was using an adze. Suddenly those who were near the two men heard the sound as of a blow, and heard the deceased cry out "Oh! oh!" A workman ran to the spot, and found Catt lying down and the prisoner standing close to him with the adze in his hand. Another witness who came up saw the prisoner move from the deceased. This witness cried out, "He has killed Jemmy." On which the prisoner said, "No, he has killed himself"; and afterwards he added that Catt had taken up his adze and killed himself. The inspector of police said that the prisoner called to him and said he had something to report, and went on to say, "I have been employed in the masthouse, and when I turned round, James Catt, who was employed with me, took hold of my adze and struck himself on the head with it, seriously injuring himself." The inspector said, "He's dead, then?" The prisoner replied, "No, I don't know about that." "Where is he?" asked the inspector. "At the surgery," said the prisoner, adding, "he was a good mate, a good workman, and a good fellow." The inspector read over to the prisoner his statement, and he said it was correct.

These, then, are the bare facts. The homicide was undoubtedly the act of the prisoner. When arraigned, he pleaded "Not guilty." The defence set up was that he was insane. In support of this plea, the surgeon who attends in the dockyard stated that in April, 1874, the prisoner had been under his care for a few days for swimming in the head, and again for a few days in October for melancholia. The surgeon of the police at Chatham, who saw the prisoner in custody the day after the occurrence and conversed with him, stated that he asked the prisoner, "Do you know what you are here for?" He said he had knocked his mate on the head, "and the stupid fellow fell down dead." "Then you killed him?" said the surgeon. To which the man replied, "I knocked him on the head, and he fell down dead." This witness stated that in December, 1868, he had signed the certificate for the removal of the prisoner to Barming Lunatic Asylum as a lunatic, where he remained until December, 1872, when he was discharged as cured. Mr. Joy, the medical attendant of the gaol, stated that since the prisoner had been there he had had frequent opportunities of seeing him, and had conversed with him constantly, and he was of opinion that he was of unsound mind, mad upon the subject of religion. He thought, he said, it was a sudden act—an act committed from a sudden impulse.

The medical attendant of the Lunatic Asylum at Barming stated that the prisoner's grandfather was insane and also one of his sisters, and that when he was received there in 1868 he was suffering from melancholia caused by religious delusions. He was discharged as cured, and was believed to be cured, and the certificate of his discharge was absolute and unconditional.

The judge put the question to Mr. Joy—"Do you think that he knew, when he struck that blow with the adze, that it was likely to kill the man?" Mr. Joy replied—"No doubt he knew that, but I believe the act was uncontrollable." To the evidence that the man had been in a lunatic asylum, the judge observed that he did not see how this affected the question. "The man," he said, "may be mad—I assume that he is so in the medical sense of the term; but the question here is whether he is so mad as to be absolved from the consequences of what he has done. He is not so absolved, though he is mad, if he was not so mad as not to know what he was doing, or not to know that he was doing wrong." And, in summing up, the judge said, referring to the report of the judges on M'Naughten's case, "this had been declared to the House of Lords by the judges of England many years ago, and by the law so declared judges and juries were equally bound." It is unnecessary to cite the well-known terms of the report. Their purport is expressed with sufficient accuracy in the passage quoted.

It being granted, then, that it made no difference whether Blampied was mad or not, it is superfluous to insist upon the evidence that he was mad. We may, therefore, merge his particular case in the general question. We may start with the fact that the law of England, like that of all other civilised countries, recognises that irresponsibility is the inherent attribute of insanity. The admission of the plea of insanity establishes this point. *Primâ facie*, then, to establish insanity is to establish irresponsibility. Upon medical science it falls to make good this *primâ facie* case. And, having done this, it is the universal contention of those who have made lunatics and insanity their study by clinical observation and other methods of research, that they have done enough. They know the absurdity of attempting to reconcile reason and unreason, health and disease. They know that insanity, where it exists, leavens the whole mass. They know that a diseased organ cannot work healthily. Observation tells them that man, complex though he be, cannot be sane and insane—that is, responsible and irresponsible at the same moment. Cases, indeed, there are, but they are not common, in which monomaniacs, as they are called, may appear sane until their particular delusion is hit. But it is a gross and dangerous, albeit a popular error, to conclude that these persons are really sound even in part. They are more or less under the dominion of their craze; it underruns the whole current of their thoughts, and may at any moment sway them irresistibly.

We do not know that the illustration has ever been used, but it seems not inappropriate to apply the creed of phrenology as the foundation of the legal doctrine of combined sanity and insanity. If we suppose the mind to be made up of distinct faculties—as perception, comparison, volition, and so forth,—each faculty having its own separate organ, it is easy to conceive that one of these faculties may suffer alone when its particular piece of brain is diseased. Lawyers, then, are phrenologists. We do not know how far they will thank us for this suggestion. It is, however, the best explanation that can be offered of their theory. They will find no support for it in true science. In truth, they do not appear to care to base their theory upon science of any kind. Their famous creed is pure dogmatism—an admirable example of the absolute *sic volo, sic jubeo.* When Mr. Justice BRETT emphatically said that the law, as he expounded it, "had been declared to the House of Lords many years ago, and by the law so declared judges and juries were equally bound," he really uttered what may challenge criticism. In the first place, what the judges declared was their interpretation of the law, and not the law itself. We hold ourselves at liberty to question whether this interpretation is the just one. In the next place, the fact that this declaration was "made many years ago," whatever the consecrating effect time may give in the legal estimation, is rather presumptive of error. Science is in its nature progressive; and this, a scientific question, clearly demands reconsideration. Law, on the other hand, built largely upon precedent and authority, is in its nature stagnant. But it must in the long run yield to the force of knowledge, and remodel its doctrine and practice in conformity with science.

The declaration of the judges hangs upon an impossible postulate. No man that has been at one time sane, and therefore trained in accordance with the modes of thought of his fellow-men, can, even on becoming insane, be freed altogether from the influence of that training. The sense that killing is wrong may remain. And it is transcendently absurd to look for a man so demented as not to know that striking another on the head with an adze is likely to injure or to kill him. Such a man can hardly be found in a lunatic asylum, and, *à fortiori,* can hardly be found out of one. He is not a creation of nature, but a legal fiction. Carried to its legitimate applications, the legal doctrine would abrogate the law of irresponsibility on the ground of insanity. The doctrine is therefore judges' law, not statute law.

Had juries invariably accepted this doctrine, and acted upon it, the exhibition would long before this have been so revolting that it must have been revised. Fortunately, juries, supported more or less by public opinion, have been, intermittingly, it is true, engaged in tempering this doctrine in practice. This moderating influence is always at work. The judges may still assert what they declared "many years ago." But it is less easy to induce juries to obey them. Through juries science often speaks. Sensible men will, in spite of strong dictatorial charges, take their medical and other scientific instruction from experts, and not from lawyers. In this way the famous interpretation of the law has been deprived of much of its evil force. It is becoming practically obsolete, and must at no distant date be given up even by the lawyers.

◆

AT the Marylebone County Court a case was decided on the 20th inst. which is important in that it defines to some extent the fees to which a medical practitioner is entitled for his constant attendance upon an important case after surgical operation. The facts are briefly as follow:—

In the night of the 1st of March of the present year, a little boy five years of age, the son of Herr BEHRENS, the well-known bass singer of Her Majesty's Opera, was lying at the point of death from diphtheritic croup and laryngeal obstruction. Dr. WILBE, of Finchley-road, who was in attendance, summoned Dr. RICHARDSON, who came and immediately performed tracheotomy. The operation gave direct relief, but as it was foreseen that in the course of the case there would be great difficulty in keeping the artificial opening clear of secretion and false membrane, and as Dr. WILBE's professional avocations prevented his own constant attendance, the services of Mr. T. OTLEY LOVELL, who lived near, and who had assisted Dr. RICHARDSON in a similar previous case, were obtained. In order to give every possible chance of success at a moment so critical, Dr. RICHARDSON fitted up and left at hand his apparatus for artificial respiration after tracheotomy, in readiness to be used at any moment should the natural respiration cease, and Mr. LOVELL was left in responsible charge to carry out whatever was decided on at the different consultations that had to be held. In this duty he was relieved at intervals by his brother, also a qualified practitioner; and it was proved in evidence that the attendance thus rendered by the Messrs. LOVELL extended over one hundred and thirty-two hours. In the course of this time the tracheal tube was repeatedly blocked by secretion, and but for the constant and skilled attention of the watchers the child would have been suffocated; at one moment, in fact, the natural respiration of the patient actually stopped, and the application of the artificial respiration by Dr. WILBE and Mr. LOVELL brought back life when to all common observation the child was dead. In the end a complete recovery rewarded the anxious efforts of Dr. RICHARDSON and his colleagues. At the close of their attendance Mr. LOVELL sent in an account for his services, at the rate of five guineas for every twenty-four hours of attendance. To this Herr BEHRENS objected on the ground that the sum was too heavy; whereupon Mr. LOVELL at once reduced his terms to three guineas for each twenty-four hours, the sum total of his account being seventeen pounds seven shillings and sixpence for the whole attendance. This reduced account Herr BEHRENS still refused to pay, and hence the action at the County Court before which Mr. LOVELL, by his counsel Mr. PATERSON, contested his claim. In the defence no pretence was made that the plaintiff was unable to pay, neither was the sum named for the service rendered now pleaded as excessive, but an attempt was made to show that the whole period of one hundred and thirty hours was not passed by the plaintiff and his brother in the sick room. It was urged that in the course of the attendance the patient was left for twenty-six hours, so that technically the attendance extended to one hundred and six hours only. The evidence of the Messrs. LOVELL proved that, except for short intervals, when they went home, and even then were ready to be called, they never left the patient unattended; and Dr. RICHARDSON came forward to give hearty testimony to the devotion and perseverance with which they had carried out every detail that had been entrusted to them. He also, together with Mr. TIMOTHY HOLMES, Dr. CLEVELAND, and Mr. WEBB, expressed to the Court the opinion that the original charge of five guineas for each twenty-four hours of attendance was a fair amount, and that the reduced fee of three guineas was most moderate. An effort to depreciate the value of the services rendered by Mr. LOVELL signally failed. "Do you mean," the advocate for the defence asked Dr. RICHARDSON, "that you took Mr. LOVELL into your consultations?" "Certainly," was the answer. "But you do not mean to say you accepted any suggestions from him?" "Yes, some very useful suggestions," was the instant reply. In the end the jury, after hearing the advocate for the defendant, the counsel for the plaintiff, and the summing up of the judge, decided at once for Mr. LOVELL for the full amount, and costs were allowed.

We have stated these facts at some length because they afford a decision on which what may be called the minimum fee for constant day and night attendance by a medical practitioner may in future be based. This point has never, as far as we know, been decided before. An attempt was made by the counsel for the defence to extract from Mr. HOLMES and Dr. RICHARDSON that the fee in such a case was a mere fancy sum; and the latter gentleman's fee for the operation and after-visits, which the plaintiff said he had not yet paid, was adduced in order to show that it was very much less than it would probably have been if the child whose life was saved had been the son of a wealthy man. But the argument did not prevail, and what we must consider a minimum rate of charge to persons who, though not wealthy, are certainly able to pay for important professional services, when they can be brought under the hand of the law, was thus defined.

A conspicuous feature in this trial, and one we cannot omit to name, was the summing up of the judge, Mr. Serjeant WHEELER. With singular lucidity of statement and decision his Honour told the jury that, in a judgment such as was before them, they must take into consideration, not merely the time of the service rendered, but the importance of the service. He had calculated that, for the duties performed in the hundred and thirty-two hours during which they had been substantially in attendance, the Messrs. LOVELL had asked for the sum of two shillings and sevenpence per hour. A surgeon working night and day at this rate, in ordinary practice, would not earn more than a thousand a year, and it could hardly be expected that, for a service so purely exceptional as had here been rendered, a less than ordinary fee should be demanded. In a word, if his Honour had understood practically what it is, in the way of service, to carry out the details of treatment of a terribly infectious disease for a hundred and thirty-two hours, to see for that time the peril of the patient, and to hear for that time the anxieties of parents and friends, he could scarcely have expressed with better feeling and judgment the weight of the responsibilities that attach to the professional attendant, or the spirit in which those responsibilities should be received. We venture, in the name of the profession, to thank Mr. Serjeant WHEELER for his kindly appreciation of us and of our labours. It is not often we receive so much consideration, and it is the more welcome in the present instance because it comes to us with the weight and calmness of judicial authority.

◆

IN a letter to *The Times* of July 22nd, Mr. GEO. POLLOCK directs the attention of the public to the relative dangers of ether and chloroform as general anæsthetics. Whatever comes from the pen of Mr. POLLOCK is certain to secure attention, for the *vis familiæ* which has made his name so thoroughly a household word in this country is characteristically present in every sentence. The fact makes it the more regrettable that Mr. POLLOCK should have chosen the leading journal for his letter, in preference to the journals that are strictly devoted to the discussion of topics of a purely scientific and professional order. It is the wanton fate of all medical scientific communications made to the general newspaper that they call forth at once a number of weak and very irrelevant statements and opinions on which the public can form no correct judgment, which in the end excite alarm, and which confer no trace of reliable knowledge. The public finds itself suddenly in the midst of an argument without being supplied with the premises, and without being familiar with the authorities on whom it may rely. In one sentence, uncompromising in its reading, Mr. POLLOCK asserts that, while the administration of chloroform is by no means "unfrequently fatal, even when administered by experienced hands," the other anæsthetic—ether—"may be used most freely, is devoid of danger when pure, and has never been known to destroy life." In another sentence Mr. POLLOCK informs his readers that this "is a big subject," and, in continuance, he suggests significantly that it is a subject which judges, coroners, and magistrates may have to deal with in connexion with the practice of the professors of the healing art.

We believe that Mr. POLLOCK has stated one side of the "big question" with too much emphasis; and that he has omitted to mention many facts on the other side which would materially modify any opinion that would be delivered by a judicial mind upon all the facts. The relative safety of ether and of chloroform, as at present understood, is, as we have already admitted on former occasions, in favour of ether. This has been the experience of all of us who, from the first introduction of anæsthesia, have followed the history of the subject. SNOW, who commenced by administering ether and moved from that agent to chloroform, admitted the greater safety of ether; and, with his usual fondness for simile, described ether as the tinder-box and chloroform as the lucifer-match—by which he meant to convey that ether is the clumsiest and at the same time the safest agent. But these admissions, which after all are based on imperfect data, are very different, as they deserve to be, from the out-and-out statement that ether administered for anæsthesia has never destroyed life. Within a few months after its introduction—viz., in July, 1847—a pure death from ether took place at the Hôtel Dieu d'Auxerre; and in the course of the same year other deaths, assumed to be from ether, and certainly on as good evidence as has been often assigned since in relation to deaths attributed to chloroform, were reported in this country. The effect of these untoward events at the time they occurred was startling, and shook the confidence of the profession in the use of ether so seriously that if chloroform had not been introduced we doubt whether general anæsthesia would have held its ground at all. Chloroform came, we had almost said, to the rescue, and with its employment a given and calculable mortality. At length the mortality, made matter of certainty by repeated experiences extending over twenty-six years, having created a natural alarm, the discarded ether has reassumed to some extent its original position, to receive in its turn its original estimate, to be proved much less handy and much more expensive than chloroform, and to be attended with death from or during its action. Within a period of a few months, in this kingdom alone, a youth has died simply from the effects of ether; two adults have died during its action, if not from it; and more than one case, of all but fatal character, has been observed.

It follows, then, that the absolute safety of ether is not proved, and though we incline to think that it is safer than chloroform, the wish that it is may, after all, be the parent of the belief. In plain truth we have no data on which to base a perfect conclusion. Ether has been administered in so infinite a number of times less than chloroform that it is impossible to reckon the relative mortalities from the two agents. If we were to compare the chloroform administrations by a hundred to one over the administrations of ether we should certainly not be exceeding the mark, and although we believe that chloroform kills at the rate of one to every two thousand five hundred who inhale it for anæsthesia, we are able to arrive at this approximate number by a calculation only of a number of cases of which no tithe has been presented on the side of ether. We doubt whether up to the present time one hundred thousand administrations of ether could be shown; and if all the deaths during its administration for that number of times were recorded, they would still afford insufficient data for comparison with chloroform. We deal, therefore, with no more than a general impression when we say ether is safer than chloroform. Such an impression is commonly correct, but it is not exact, and in accepting it a considerable licence must be permitted, for it may be wrong. Any way, the time has not yet arrived for putting it forward in the light of a proven fact of science, nor will the time arrive until the practice of the administration of ether shall become as universal as is now the rival practice of the administration of chloroform.

We are driven unwillingly to make these comments on Mr. Pollock's forcible letter. Neither ether nor any other known general anæsthetic yet discovered is absolutely safe when it is administered to the extent of completely destroying sensibility, and it is but fair to all our brethren, who, guided by the worthiest and best intentions, are obliged to administer the different agents for extinguishing pain, to declare this truth.

◆

It is satisfactory to know that the attention of the practical mind of Mr. Cross has been directed to the case of the child Emma Plain, who was attended by an unqualified practitioner at a dispensary in Islington, and who died under the treatment there received. In answer to Mr. O. Lewis, the Home Secretary said "his attention had been called to the verdict of the jury at the inquest upon the body of Emma Jane Plain, aged nine months—viz., that while they found that the death was from natural causes, they pointed out the fact that the deceased received medical treatment at a dispensary in Copenhagen-street where medicines were administered by an irresponsible unqualified medical practitioner. This was an unfortunate case. All he had to say about the state of the law was that the question now raised by the hon. member was discussed at the time of the passing of the present Act, whether absolutely unqualified practitioners ought to be allowed to administer medicine. The law was, that if an unqualified person held out, in any shape or form, that he was a qualified practitioner, he was liable to punishment; otherwise not. As the question was one which came within the province of the Lord President of the Council, he would call his noble friend's attention to it."

It is to be hoped that the Lord President will not think the evil illustrated by this case a slight one or one unworthy of the attention of the Government. It is, in truth, a very extensive and extending evil. A similar case has been brought to light in an inquiry by Mr. Donaldson, the deputy coroner for the Eastern Division of Middlesex. In this instance an infant child named Herbert Wilson became ill, and was taken by its mother to Bethnal-green Dispensary. The fee necessary for a week's attendance—viz., 2s. 6d.—was paid. The child was visited by Mr. Smyth, and was supposed to recover under his care. It fell ill again, however, and was taken by the mother to the Hospital for Children, where the medical officer seemed to advise her to have attendance at home. Thereupon she sent to the dispensary again. On this occasion she was attended by a properly qualified medical man, instead of Mr. Smyth, who was unqualified, but who told the jury that he was part proprietor of the dispensary, and had "a properly qualified medical man, Mr. M'Gill, who did half the prescribing, and the remainder was done by himself as assistants would do." We hope Mr. M'Gill feels flattered by occupying this relation to Mr. Henry Beardmore Smyth. Finally the child was seen by Dr. Sarvis, the medical officer of health for Bethnal-green, who considered it to be labouring under pneumonia after measles, of which it died. Whatever Mr. M'Gill's feelings may be in regard to his relations with Mr. Smyth, it is a serious thing, at variance with the interests of the people and with the intentions of the Legislature, that they should be thus deceived at a quasi-medical institution purporting to supply them with duly qualified medical attendance. Mr. Beardmore Smyth himself says that half the work is done by himself, and that he is not qualified. Just as Mr. M'Gill might speak of having an unqualified assistant, Mr. Smyth speaks of having a qualified medical man. This case is different from that of a general practitioner who has an unqualified assistant acting in strict subordination to himself. Here the unqualified man is part proprietor, and does half the work. We are not going to argue that if this child had been attended throughout by a properly qualified medical man, the insidious accession of the pneumonia would have been perceived and prevented. Such cases are difficult enough of treatment even for qualified medical men; how much more so must they be to the unqualified. But the point of these cases is that, in a way not contemplated by the framers of the Medical Act, the public are in fact deceived by the use of certain words on signboards or on brass-plates. The Medical Act forbids specifically the false use of titles, such as that "of Physician, Doctor of Medicine, Licentiate in Medicine and Surgery, Bachelor of Medicine, Surgeon, General Practitioner or Apothecary," or any other name, title, or description implying that the person using them is registered under the Medical Act, or that he is recognised by law as a medical man. Men like Mr. Ker and Mr. Henry Beardmore Smyth know this very well, and avoid the use of such titles. But they set up a sign on their house, and call it a "dispensary" or a surgery, and announce hours of consultation and terms of attendance; and it is amply proved that whole classes of people, whole neighbourhoods, are deceived by these expressions into thinking that they are receiving the advice and the medicines of men with the *imprimatur* of the State upon them. It is for statesmen to consider whether the law cannot be so amended as to make it illegal to give misleading titles to houses or buildings, or in any other way to get money out of people for medical purposes under false pretences. A surgery implies a surgeon, a dispensary a qualified medical practitioner capable of giving medical advice, and such words mislead the public almost as effectually as the false use of personal titles. The members of the medical profession are greatly injured by such devices, and it is hard that they should be, considering at what a cost they purchase medical titles and privileges. This may seem a slight matter to our legislators, but they cannot disregard the proof or think lightly of the fact that cases of serious disease are taken to perfectly unqualified practitioners under the delusion that they are regular medical men, and that the present state of the law is such as to permit of such deception being practised with considerable chance of impunity.

◆

The Middlesex magistrates, in the exercise of their wisdom, determined, at their last meeting, held on July 22nd, to refer to the Parliamentary Committee an amendment of the Coroners' Act. The chairman, Captain Morley, trusted that the Committee would recommend that coroners should be appointed by the Crown, that they should be paid by fixed salary, that they should be barristers-at-law, that the Courts of Quarter Sessions should have the power of refusing to pay the costs of unnecessary inquests, and that the coroners should be set in motion by the police and should direct their warrants to police constables. If the Middlesex magistrates would have the prudence to extract the clause for suggesting barristers as the judges most fitted to inquire into causes of death, and the modesty to add a clause that would exclude themselves and all other magistrates from interference with coroners, the recommendations would be of value. But whether Parliament will ever be persuaded to take the power of election of coroners out of the hands of the people, and place it in those of the Crown, is a question which the Middlesex magistrates may take time to consider. It will fill up with advantage all the time during which their own magisterial existence is permitted and sustained.

Annotations.

"Ne quid nimis."

THE NEW CHILDREN'S HOSPITAL.

On Monday the new Children's Hospital in Great Ormond-street, which has just been completed after designs by Mr. E. M. Barry, was thrown open for a "private view," and was visited in the course of the day by large numbers of persons.

There is not room for two opinions as to the very high architectural merits of the new buildings, which cannot be said to belong to any one style of architecture, but combines many of the best qualities of Byzantine and Tudor. The material is of red brick, and much use has been made of terra-cotta for ornamentation. Although the building is ornamented in the highest degree, ornament has almost everywhere been made subservient to utility, and the public will have no cause to complain that their money has been frittered away upon purposeless decorations.

The building is oblong in form, and consists of a central block (which contains, in addition to the hall and staircase, the chapel, operating theatre, ward kitchens, and officers' rooms) and two wings, which are entirely devoted to the patients' wards. The wards are floored with teak, which is to be semi-polished; the walls are of glazed brick of different colours, and the ceilings are of white Parian cement. Beneath the white ceiling, and at no great distance from it, hangs the gas-lamp of seven burners, which in a very short time must blacken the white Parian which at present looks so cleanly. Why some modern form of gas-lamp which carries off the products of its own combustion was not chosen we are unable to say. The heating is partly by hot-water pipes, and partly by a Galton's stove in the centre of the ward. The ventilation is by the windows, of which there is a row on both sides, and by special ventilating apertures above and below them, and also in the ceiling. A great feature in the construction of the wards are the balconies which flank them on either side, and which will serve as charming airing-grounds for the little patients. The closets, lavatories, and sinks are quite outside the wards in octagonal towers, which have their own arrangements for ventilation, and which are one of the chief ornamental as well as sanitary features of the building. In the roof of each closet, just over the gas-jet, is the aperture of a flue which runs in the wall of the turret to its uppermost chamber, which is elevated several feet above the general level of the building. Ventilating shafts from the soil-pipe of each closet are also carried in a similar manner to the upper chamber of the turret, which is kept always heated by a stack of iron pipes, which are in constant connexion with the hot-water service of the hospital. In this way a constant up-draught is maintained, and a thorough ventilation of the closets and soil-pipes is ensured. In winter the wards are supplied by a constant stream of heated air passing through shafts which are in direct communication with the open air into the centre chamber of the Galton's stoves, which stand in the centre of the ward. The drains of the hospital enter the main sewer at two points, which are each guarded by double traps; and between the traps there is a ventilating shaft, which runs with the other sewer and closet ventilators to the upper heated chambers of the towers. The attic storey is devoted to the nurses' bedrooms, which struck us as being none too large, the cubic space provided for two nurses being on a rough but liberal calculation about 1400 ft.

There are all the best modern appliances for the saving of labour in the shape of pneumatic bells, speaking-tubes, cooking-ranges, dust-shoots, coal-lifts, and dinner-lifts, the attention paid to details of this kind having been most minute. The mortuary and post-mortem room are not complete, and the resident officers' apartments were not open for inspection.

The out-patient department, with the dispensary and kitchen, is in the basement, and every effort has been made to facilitate work and prevent confusion. The hospital provides accommodation for 112 patients, and contains special wards for whooping-cough and cases of infectious fever which may occur among the inmates, as well as private wards for cases requiring absolute quiet or special attention.

One of the great attractions to the visitors on Monday was the chapel, which is a perfect gem of ecclesiastical decoration, in which alabaster, mosaics, stained glass, and metal-work vie with each other to charm the eye. This chapel is the gift of an anonymous benefactor, and no part of its decoration has been paid for out of the ordinary funds of the institution. There can be no doubt that in its new building the Children's Hospital will pursue its career of charitable and scientific utility for which the public and the profession have alike been its debtors for the past twenty-five years.

NURSING.

THE publication of a Report from the Sub-committee of the National Nursing Association recalls our attention to this very important subject. This report shows in detail, and most truthfully, how many lives in all grades of society are annually sacrificed because persons cannot be found to carry out skilfully and faithfully, as well as tenderly, the advice and directions of the physician. This want affects rich and poor alike. Many of those who live in palatial establishments, and are able to obtain anything and everything that money will buy, have experienced the sad fact that the lives of those nearest and dearest to them have been lost because the careful conduct of the nursing was not properly provided for. And the same want exists in the homes of the poor. If we compare ever so roughly the work done in the out-patient and internal departments of our large hospitals, and consider that the patients prescribed for in the former are wholly without the means of obtaining one important essential to recovery—skilled attendance,—it will show, if no other reason existed, that a large proportion of the advice and medicine given is hopelessly wasted. The report, which appears to be chiefly the work of Miss Florence Lees and Mr. Rathbone, aims high, and a programme is sketched out that will require much continuous labour and skill to carry out successfully. A training school is proposed in close connexion with a hospital, a district home in the vicinity of the hospital, and responsible to the training-school, which home shall, so to speak, nurse the district immediately surrounding it, and also send out nurses to other districts. A year's hospital training and three months' work in the "head quarters" district home are to qualify for the certificate of competency. It appears to us that, in the first instance, a beginning might be made by requesting all the chief hospitals, both in London and the provinces, to receive a certain number of probationers, who would, under proper supervision, acquire the rudiments of their art, and after an interval proceed to the training-school for special as well as practical study. Of one thing we may be sure, and it is that all hospital authorities should aid and second, as far as possible, the efforts of this Association. The work will of course be conducted apart from all sectarian or special religious proclivities, so that on this score no opposition can be fairly raised by the governing body of any institution. But we would repeat in effect the observations made in May of last year, when the Association was commencing preliminary arrangements, that, in our belief, the raw material for nurses is not so abundant as appears to be generally supposed. Nursing is laborious and risky, and involves a large expenditure of patience, tact, and temper. But the best material for the manufacture of good nurses will probably be found among the middle classes, in which there are hundreds of well-bred and fairly educated women who, in making this work their study, may ennoble it and themselves at the same time, and relieve a vast amount of human suffering in all walks of life.

THE CHESTER INFIRMARY.

Two questions of some delicacy and much interest have been discussed at a special general meeting of the governors of the Chester Infirmary. One took the form of a proposal to reduce considerably the number of recommendations for in- and out-patients allowed to subscribers, in consideration, first, of the greater cost of everything used by the sick, and, secondly, of the principle (happily becoming more and more recognised) that true charity consists in supporting an institution where the neediest are helped in preference to the less needy. In the case of hospitals, clearly the only judges of the fittest cases must be medical men. To the credit of the governors of the infirmary, this proposal was carried.

The next question came up as a result of the resignation of Dr. Waters as a physician of the infirmary, after an honourable service of twenty-five years. It had reference to the qualifications of candidates for the post of physician to the hospital. The bye-laws require that the candidates shall be graduates of certain universities. The rules which prescribe the qualifications of physicians in country infirmaries —and in London hospitals, too, for that matter—are just a little out of date in this advanced period of the world, and in this age of reciprocity in British medical qualifications. In some London hospitals, for example, it is of no use for a graduate of London or Edinburgh to apply for a physicianship unless he is also a Member of the College of Physicians of London. This rule is good for the London College, but bad for the hospitals, and perfectly indefensible on principles of justice. It is a relic of protection and a bygone period. The Chester rule seems far more defensible. A guarantee of some extra examination and education is demanded, but it is accepted from any quarter of the kingdom in the natural form of a degree in medicine, which can scarcely now be acquired in Britain without some pains and merit. A more doubtful law, though only of custom, has hitherto obtained in Chester. For a long time the *lex consuetudinis*—not the written law of the hospital—has required the holder of the office of physician to abandon general practice and practise as a pure physician. Such a law may operate very hardly in a provincial town. As a rule, hospital physicians should gradually abandon competition with general practitioners. Such is the *prestige* and privilege of their position that it is obviously both fair and dignified that they should tacitly take it for granted that they are not expected to practise as general practitioners; but to expect a young physician all at once to abandon general practice for an infirmary appointment is unreasonable. Such self-denial is not expected of hospital surgeons. There are some towns in which eminent hospital surgeons give advice and medicines on very low and undignified terms. The law of custom in Chester was nearly universally condemned. We think rightly so. Henceforth no meritorious general practitioner will be hindered from competing for a physicianship by the alternative of having summarily to abandon his practice, perhaps the work of many years of toil.

THE DISPOSAL OF THE DEAD.

OUR Transatlantic neighbours, if not original writers, are very excellent and industrious compilers, and we have before us an article on the relative advantages of cremation and burial that, as to the bibliography of the matter, assuredly rivals any treatise on the same subject that has up to the present time been published in this country. The author, Dr. J. F. A. Adams, of Pittsfield, Massachusetts, describes *seriatim* the history of cremation in ancient and modern times, intra-mural interment, and interment at the present day, the object being to show whether cremation is a practicable and safe method, and if so, whether the evils necessarily resulting from burial are so great as to demand a change. Time and space do not permit us even to recapitulate here the historical aspects of the article, though they are exceedingly interesting, and well worthy of perusal. The author having described the various methods of cremation as proposed in modern times, and particularly those devised by Sir Henry Thompson and Siemens, concludes that it may be made a complete, rapid, and inexpensive process, in no way offensive to bystanders, nor liable to contaminate the general atmosphere. It is enough to state that the history of intra-mural interment and its effects is largely drawn from the reports of Mr. Edwin Chadwick, Professor Brande, and others, made between 1843 and 1851, "the effect of which was so convincing that a change was at last brought about by legislative enactments." The notes on interment as practised in the present day include the regulations prescribed by law for the depth of graves in all European countries as well as in America, and the special rules in force in England. An effort was made by the author to discover the influence wrought by extramural graveyards on the quality of the well-waters surrounding them, as influencing the origin and spread of epidemic disease. Categorical questions referring to these two specific points were sent to upwards of four hundred scientific persons in the States and in this country. An analysis of the replies is given, and some (notably that by Mr. P. H. Holland, Medical Inspector of Burials for England and Wales) are printed in full. As a result (and an important one as bearing upon cremation) the author is "greatly surprised at the small amount of evidence we have been able to gather of any positive injury known to result from burial-grounds." Five cases only of possible or probable harm done by proximity of dwelling-houses to cemeteries are cited as having occurred in America, and two or three only "possible" cases in other countries. Great stress, of course, is laid upon the recorded opinions of Mr. Holland and Dr. Cameron of Dublin, both of whom are, as our readers know, firm believers in the absolute harmlessness of burial if properly performed. The third question put to correspondents related specifically to analyses of well, brook, or other water obtained from the vicinity of cemeteries. The deduction drawn from fifteen analyses was that wells in or near cemeteries enjoy an especial immunity from contamination, inasmuch as their position renders them less likely than others to be tainted by privies, drains, and cesspools. The author says that Fleck's examination of Dresden wells has led him to the same conclusion, and adds, "We have been unsuccessful in obtaining a single example of disease presumably induced by water contaminated by the proximity of burial-grounds, although the evidence that a great amount of disease, especially typhoid fever, is induced by drinking water polluted by drains, privies, and cesspools, is constantly accumulating." In other words, a living man in sound health is far more to be dreaded as a disease-producing agent than is a dead man buried with ordinary care.

Dr. Adams, obviously enough, arrives at the conclusion that "cremation is an innovation not demanded in this country (i.e., the United States) on sanitary grounds, but there is no reason why its adoption should not be optional with all persons." The article, as we indicated above, should be read carefully by all interested in this question. *Audi alteram partem* is a sound motto. We think the sum total of data and opinions upon which the author bases his conclusion inadequate for the purpose, and not sufficiently exact. The historical are, in fact, better than the sanitary and statistical parts of the essay, which is included in the Sixth Annual Report of the State Board of Health of Massachusetts.

Last week Dr. A. J. Bernays, Professor of Chemistry at St. Thomas's Hospital, called attention in *The Times* to a modification of Mr. Seymour Haden's plan of burial, proposed by the writer in a lecture delivered in October of last year. Assuming that the English public will never give a general consent to cremation, Dr. Bernays believes that the best way of bringing about harmless decay would be by burning the soil, if clay, so as to render it permanently porous, and enclosing the body in a coffin made of perforated iron plate, with a lid of the same material. Such a coffin would resist pressure for several years, and the signs of oxidation on the part of the iron would communicate themselves in a visible manner to the drainage from the cemeteries. The bottom of the grave is to be covered with charcoal, and filled in with the burnt clay to the depth of six feet.

THE ARMY MEDICAL SERVICE.

THOSE who have repeatedly scanned the published reports of Mr. Hardy's utterances with the view of extracting something hopeful in regard to the future of this service, need scarcely be reminded that anything which may have been promised has been expressed in very general and vague terms, and always with a view of getting rid of some troublesome deputation, or of affording an answer to some questioning M.P., or to avoid, as on a recent occasion, a division on a motion. As we have said more than once, Mr. Hardy appears brimful of good intentions, but he takes very good care to conceal the shape and character which these are likely to assume. His intentions may be, after all, only apparent. He has certainly told us what we are not to expect, and that is about all. Moreover, even if Mr. Hardy had at this moment drawn up an excellent Warrant, which is very doubtful indeed, it will have to surmount a sea of difficulties and opposition before it sees the light. A correspondent reminds us that many years ago an excellent Warrant was in type, but a large number of medical candidates was forthcoming, and the type was thereupon, we suppose, at once broken up, for no Warrant appeared. Under the late administration we all know what happened. No one would think of calling the last Warrant an excellent one. The moral of all this is that before young men enter the army they should know positively and definitely what is to be done, and not trust to a vague sort of hope and belief that something or other will be done. In the present state of uncertainty as regards all that concerns the Army Medical Service, that of the Navy unquestionably holds out the best prospects. There is, of course, considerable difference of opinion as to the merits of the late Naval Medical Warrant, but we consider that it is, on the whole, a good one, and our judgment in this respect has been strengthened and confirmed by all that we have heard. Mr. Hardy having stated that he has no objection to the probable number of vacancies in the Army Medical Department being stated at the time when the competitive examination is announced, we shall soon know whether the number of candidates does not fall short of the requirements of the service.

THE TROOPS AND THE WEATHER.

THE Autumn Manœuvres that have just terminated have been carried out under conditions of weather of a very exceptional kind. The rain has been so persistent and occasionally heavy as to have resembled the rainy season of a tropical climate more than an English July. The troops have had anything but a good time of it. After marching in rain, and returning to camp fatigued and soaked to the skin at the end of a day's work, they have found their tents flooded, the ground so damp as sometimes to compel them to stand up all night instead of lying down, and with no change of garments. Still their health has been very good, the amount of sickness being insignificant. The meeting of the National Rifle Association at Wimbledon from the 12th to 24th inclusive, will also long be remembered as the wettest on record; indeed, we heard of a placard having been displayed by some humorous individual advertising that a swimming match was to be held. The discomfort and the interference with enjoyment were doubtless great, but the wet exercised no injurious influence upon the health of the men. The average daily sick, out of an average strength of 2906, was only 5·44, or about 1·80 per thousand; the total number receiving treatment being only 24, and the majority of those were slight cases of cuts, sprains, burns, and other accidental injuries. The volunteer hospital was empty during the whole period. Surgeon-Major Owen calls attention in his report to the fact that in 1867, also a wet season, the sick-list was small. Diarrhœa, the most frequent camp disease, may, he thinks, be attributed generally to heat, exposure to the sun, variations of temperature, increased thirst, and irregularities of diet—causes which are in a great measure avoided in wet weather, spite of its disadvantages. In 1868 it was exceptionally hot, and, with an average of 2159 campers, the applicants for treatment were 439, of which number 309 were for diarrhœa alone. The sanitary condition of the camp this year has been very good.

DEATH FROM CHLOROFORM AT QUARRY BANK.

A WOMAN, aged twenty-one years, died at Quarry Bank, on July 7th, while under the influence of chloroform, administered for the operation of puncturing an abscess in the abdomen. The patient was under the care of Mr. Ker, of Cradley Heath, who had diagnosed a circumscribed abscess, and was about to operate when violent vomiting came on. The chloroform was withdrawn until the vomiting had ceased, and the patient meanwhile became partially conscious. Before the chloroform could be again administered she gave a gasp and died. The chloroform was given by Mr. E. Sainthill Pearse, who agreed with Mr. Ker in believing there was circumscribed abscess, and that the operation was necessary. Mr. George Ashmead, of Brierly Hill, who made the post-mortem examination, deposed at the inquest that the heart of the patient was healthy and the cavities empty, that the lungs were extensively diseased, that a large cavity containing pus existed in the right lung, that the left lung was consolidated, and that there were extensive pleuritic adhesions. The liver was softened, and a quantity of pus was found in the peritoneum as the result of peritonitis. Mr. Ashmead was of opinion that the pus in the peritoneum was not circumscribed during life, while Mr. Ker believed it was, and that the syncope, from which the patient died, was from rupture of the abscess into the peritoneum. The jury returned a verdict that the deceased died from suffocation, caused by impeded circulation of the blood; and the coroner, who looked upon the operation as a forlorn hope to relieve a dying woman, said that it was worse than useless to spread an alarm throughout the country as to the use of chloroform when it was considered that the deceased was in such a state that she might have died at any moment. Not the slightest blame, he added, could be attached to the surgeons who attended. While we agree with the remarks made by the coroner on this case, and without desiring to impute the least blame to the gentleman who operated, we cannot help pointing out that it was a case for local rather than for general anæsthesia. The puncture into the abscess might have been made by the local method without the infliction of any pain, and all danger of sudden death from anæsthesia prevented. It is indeed difficult to imagine a more favourable opportunity of employing the local and safe measure for a painless operation.

ST. BARTHOLOMEW'S HOSPITAL.

THE anniversary dinner of this hospital was given by the hospital stewards on Wednesday evening. The company was large and distinguished, including Professor Owen, Sir Charles Reed, the President of the College of Physicians, the President of the College of Surgeons, Mr. Brudenell Carter, Dr. Cameron, M.P., &c. &c. The chair was ably filled by the treasurer of the hospital, Sir Sydney Waterlow. When we say that nearly all these gentlemen and others spoke from their respective points of view, we need not add that the proceedings were of unusual interest, and that a very good account was given of the hospital. It is interesting to think of this institution, originating with a prior of the twelfth century, showing no sign of decay or of age, but still at the front, whether regarded as a school or a hospital. Under the able administration of Sir Sydney Waterlow, the practical religion and administrative capacity of the nineteenth century is represented as it was by Rahere in the twelfth. "There are diversities of gifts, but the same Spirit."

CALCUTTA MEDICAL COLLEGE.

THE annual distribution of premiums and diplomas to the students of the Medical College took place at the Senate House of the Calcutta University on the 15th ultimo, when Dr. Norman Chevers, the Principal of the College, delivered an able and interesting address. In the report for the preceding year allusion was made to the very great loss which the College and Hospital had sustained in the retirement of Dr. Fayrer, C.S.I., after having been connected with those institutions for fifteen years. Dr. Fayrer is succeeded by Mr. S. B. Partridge, F.R.C.S., in the Professorship of Surgery at the College, and he becomes at the same time the senior surgeon to the Hospital. The death of Surgeon-Major Dr. Chakarbatti, one of the physicians to the Hospital and Professor of Clinical Medicine and Materia Medica, who had taught in the College for twenty-four years, was a source of sincere regret to all. Dr. Chakarbatti was a native of India, and was one of four students sent by the Government to complete their education in London, under the care of Dr. Goodeve, and being a man of much energy and ability he attained considerable eminence as a physician. The number of students educated at the Calcutta University and Hospital is very large, and it is not easy to over-estimate the amount of real practical good that is done in this way. To take a case in point. On the occasion of which we are speaking the Principal of the College presented to Assistant-Surgeon Ghose, a former student of the College and Hospital, the sanad, or patent, of Rai Bahadur, with which title he had been invested by the Government of India in recognition of a long series of services of an arduous and distinguished kind; *apropos* of which we may mention that Dr. Ghose is a very dexterous operator, and has performed lithotomy nearly 500 times, and that he has enriched the museum of the College with 200 of the stones removed by him.

THE QUEEN AND THE PROFESSION.

The profession ought to be, as we have no doubt it is, highly gratified by the kindly feeling which Her Majesty invariably manifests towards those members of it upon whom has devolved the honourable and responsible duty of guarding Her Majesty's health. A few years ago, when Sir James Clark died, the notice of his death, which appeared in the *Court Circular*, was accompanied by most gracious expressions of regard on the part of the Queen; and now, again, Sir Charles Locock's memory has been honoured by the expression of Her Majesty's genuine regard for the deceased baronet. Such sympathy between the Sovereign and the physicians of her Court shows that the profession to which they belong must hold an honourable place in the estimation of one who is looked upon as the sole fountain of honour, and it further shows how highly Her Majesty appreciates those who amidst the anxieties of extensive practice have shown themselves loyal and zealous in her service. It is but too often the case that doctors fail in obtaining from their patients any expression of gratitude even for services which have involved much hard work and abnegation of self, but it will never be said that Her Majesty forgot to render to her servants that which alone makes labour sweet, and which is always highly prized by those who are fortunate enough to earn such noble expressions of goodwill and affectionate gratitude.

THE MEDICAL DISTRICTS OF ISLINGTON.

This question still gives most unnecessary trouble to the Islington guardians and to the aggrieved medical officers. We have repeatedly referred to the extreme inequality of the area and number of cases of the respective districts; men with very extensive districts and a large number of cases getting the same salary, or nearly the same, as men with limited districts and a much less number of cases. The chief sufferers are Dr. Gardner and Dr. Ducat; the former having 600 cases in a quarter, and the latter 260 or 270, and a district covering 834 acres. These gentlemen would probably be both easily contented with a little addition to their salary, or the transfer of a portion of their work to the care of a neighbouring medical officer. Instead of this, the guardians propose to ignore Dr. Ducat's complaints and leave him to grapple with his enormous district, which in winter or in times of epidemic will make a very heavy demand on his time and strength. This is an odd way of dealing with a reasonable complaint. Dr. Gardner's case is to be met by equally dividing his district and proportionally reducing his salary. He will still be left with a larger number of cases and a smaller salary than those officers in the more fortunate districts. It really looks as if the guardians meant to punish these medical officers for making perfectly just complaints. We are sorry that Dr. Bridges should have suggested such an unsatisfactory mode of redressing the grievances of hard-working and meritorious servants. We trust that both he and the guardians will abandon a false position, and take the simple course of transferring a portion of the work of the Highbury and St. Peter's districts to other more lightly worked officers, or, if this be inconvenient, make an addition to the salary of Dr. Ducat and Dr. Gardner. The *Islington Gazette* most strongly denounces the present proposals, and it may be well taken to represent the feeling of the intelligent portion of the ratepayers.

THE HAMPSTEAD FEVER HOSPITAL.

The Select Committee of the House of Commons on this question met again on Friday last, the 23rd inst., when evidence was given by Captain Barry, Dr. Steel, Surgeon-Major Bostock, and Dr. Jervis on behalf of the Asylums Board; the object of their evidence being to rebut certain objections to the present site which had been raised by the Hampstead Residents' Committee, and to state some grounds of objection to the proposed new site.

This closed the evidence on both sides, and on Tuesday the Committee met again to consider their report, which was presented to the House on Tuesday evening by Mr. Sclater-Booth, the chairman of the Committee. Just before going to press we received the report of the Committee:—

"Having considered all the circumstances, the statements of opinion, more or less conflicting, and the ascertained facts of the case thus submitted to them, the Committee are of opinion:—1st. That the action of the Asylums Board has been strictly in accordance with their duties, powers, and responsibilities, as derived from the Metropolitan Poor Act, 1867, and from the sanction and control of the Local Government Board so far as it was incumbent on them to be guided by that department. 2nd. Without disputing the fact that some alarm was experienced and some possible risk encountered in the immediate neighbourhood of the asylum during the period of the small-pox epidemic, that such mischiefs have been much exaggerated; that they are not of necessity incidental to the existence of the hospital, but only due to the carelessness of persons entering or leaving the same, or to the imperfect control which follows overcrowding, or otherwise may at times have been occasioned. 3rd. That on the whole there is no reason why this particular district should claim the interference of Parliament for the removal from it of an inconvenience to which it has become subject by reason of the due execution of the provisions of a wise and beneficent law."

We defer our remarks on the report until next week.

METROPOLITAN POLICE-CELLS.

The subject of the metropolitan police-cells was brought before the House of Commons last Friday by Sir W. Fraser. We have recently reported specially on the condition of these cells, and it will be remembered that our report was favourable. Sir W. Fraser stated that men charged with being drunk were placed in a cell to lie on an asphalte floor or on a bench without a ledge. Our Commissioners, however, found that in all the cells they visited a sloping wooden floor was provided for persons incapably drunk, and on which they seemed peacefully to recline in their drunken slumbers. Sir W. Fraser also commented on the hardship of a "technically innocent man" being submitted to the "torture" of the police-cell for thirty-six hours. Our Commissioners, from an inspection of the police records, found that such instances were extremely rare, and that, as the accommodation was amply sufficient, it was easy to secure such isolation. Moreover, in all bailable offences security was at once taken, and the prisoner released. Sir H. Selwyn Ibbetson, in reply, quoted the statements of our Commissioners, and added that proper provision was made for exceptional cases of overcrowding.

EPITHELIUM OF THE ALVEOLI OF THE LUNGS.

DR. E. AUFRECHT describes the changes undergone by the epithelium of the alveoli of the lungs in broncho-pneumonia. He finds that near the focus of the disease the cells are much swollen, and have become opaque in consequence of fatty degeneration, and broken down, so that only fragments of them remain. In other places they have fallen away bodily, leaving a delicate network, which appears to be a modification of the cementing substance by which they are normally retained in position and connected together. This network can be readily separated from the alveoli, and can then be seen to be composed of extremely fine elastic fibres, which are but slightly acted on by acetic acid. The nodal points of the fibres exhibit nuclei. The appearances presented in disease have led him to examine the normal relations carefully, and he arrives at the conclusion that even in the perfectly healthy lung the alveoli are covered with a network of elastic fibres, containing nuclei in their nodal points, and the meshes of which contain the epithelial cells of the alveoli.

SMALL-POX AT STOCKPORT.

SMALL-POX has been unduly prevalent for some weeks past at Stockport. Last Saturday, at the Borough Court-house, the sanitary authorities summoned Mary Doulin for wilfully and unlawfully exposing Margaret Carey whilst in her charge, and who was suffering from small-pox; also, as being a keeper of a common lodging-house, for neglecting to give notice to the authorities that she had a person suffering from infectious disease; and for letting lodgings without having had them previously disinfected after the reception of an infectious patient. The case was fully proved against the defendant, but the Mayor stated that, as this was the first case brought under the notice of the bench, they would deal leniently with it, and, instead of the penalty of £20, they would inflict a mitigated penalty of 10*s.* and costs for the first offence, and 5*s.* and costs for the second and third. If any further cases were brought before the bench they would be dealt with more severely. We commend the action of the Stockport sanitary authority in dealing so promptly with the infringement of the Act. At this time, when both scarlet fever and small-pox are so prevalent, it behoves the authorities of all towns to be on the alert, and enforce to the fullest extent the powers at their command to ensure the isolation of infectious cases.

THE POLLUTION OF RIVERS BILL.

WE prophesied many weeks ago that the Pollution of Rivers Bill would not be passed this session. It is now definitely numbered with the innocents to be massacred. We hope it will be satisfactory to some that the Premier expressed his regret that it was not possible to proceed with the Bill this year, although it is but faint consolation for those who suffer in purse and person in consequence of filth-impregnated streams. The statesman who pledged himself on the hustings to inaugurate a new policy of sanitation which would distinguish this Government from preceding ones cannot be said to have fulfilled his promises. He found in his struggle a powerful ally in the profession who hoped to see their rights vindicated and their importance acknowledged under the promised new era. What has been done? The time has been frittered away in quibbling over paltry Bills, while measures of deep national interest have been ruthlessly strangled. We hope that next session the Government will present a Bill based upon wider principles, which, whilst more stringent in character, will bear less heavily and unjustly on individual interests.

HEALTH OF GARIBALDI.

SULPHUR-BATHS are proving as efficacious in Garibaldi's case as in that of the Pope. The General, who is really a greater invalid, though a much younger man, than Pio Nono, takes them at Cività Vecchia itself, under conditions more favourable to their efficacy than if he remained "imprisoned" in a Roman Palazzo. A fortnight ago he could hardly move his head or bend his fingers. Now he can do both, not only without discomfort but with ease. He makes his morning meal (*colazione*) his chief one; drives out every day in an open carriage; and sometimes ventures on a short sea-voyage in a yacht. Old sailor as he is, he gains strength by contact with the briny element, as Antæus did from mother earth; and he has resumed his sanitary study of the Campagna with an energy peculiarly gratifying when we consider how much the lives of generations yet unborn may owe to that of Joseph Garibaldi.

THE PORT OF LONDON.

ON Friday, the 23rd inst., the Port Sanitary Committee of the Corporation of London made the annual visit to their extensive district, under the presidency of Mr. Hora, the chairman. The members were accompanied by Mr. Simon, Mr. Netten Radcliffe, Dr. Sedgwick Saunders, Dr. Harry Leach, port medical officer, Dr. Whitcombe, surgeon to the hospital ship *Rhin*, and many others. Mr. Simon, in acknowledging one of the toasts proposed, took occasion to comment upon the futility and absurdity of the old system of quarantine, the importance of using all means to carry out a practical and efficient substitute for it, and the energetic way in which the Corporation had undertaken and exercised their duties as sanitary authority of the Port of London. It will be remembered that Mr. Simon worked in the City as medical officer of health for upwards of seven years, previous to his appointment as medical officer to the Privy Council.

ST. THOMAS'S HOSPITAL.

WE have to record with regret that the family of one of the resident medical officers at St. Thomas's Hospital have been attacked with enteric fever, that two fatal cases have occurred, and two other children have been dangerously ill. It is a work of supererogation to point out that this must indicate local defects in connexion with the drainage system of the hospital. Having regard to the fact that the professional staff of St. Thomas's includes the medical officer of the Local Government Board and two of the most eminent authorities on the continued fevers, it is simply astounding that, as far as we can learn, no active steps have been taken in the matter. It is, in the interest of the public, proper to inquire whether any of the above authorities have been consulted, and if so, what was the result thereof.

THE Secretary of State for War will be asked in the House of Commons to obtain the opinion of the officers who superintended the recent summer manœuvres as to the power of bearing fatigue and exposure manifested by the troops engaged, especially of such of the army forces as were enlisted during the last three years respectively as compared with the soldiers of more mature age and earlier enlistment.

THE University of Rome recently instituted a special chair for Aural Diseases, and its first occupant, Professor Emilio de Rossi, has just issued his annual report. Out of 187 patients in the wards, 127 were cured, and by methods which are sometimes as ingenious as they are novel in the department of otology.

A short time back we pointed out a serious and dangerous defect in the condition of the Shoreditch Workhouse. In consequence of the want of adequate mortuary accommodation, decomposing bodies were frequently brought into proximity with the wards of the infirmary, thereby endangering the health of the patients. Last week the matter was brought before the notice of the House of Commons, when Mr. Sclater-Booth, in reply to a question, stated that arrangements were now being made which would obviate any further difficulties in this respect. It should be known that one of the provisions of the Public Health Bill, now passing through Parliament, confers on the Local Government Board the power of compelling local authorities to provide mortuaries where necessary. There are crowded districts in the metropolis and the country where the need of mortuaries is most urgent. We trust the forthcoming Act will effectually remedy such grievances.

It has been notified to us that two scholarships, of the annual value of £80 each, tenable for four years during residence, will be awarded in October next at Exeter College, Oxford, for proficiency in Natural Science. There is no limit of age for these scholarships. The examination will be in biology, chemistry, and physics, and candidates will be expected to show proficiency in two at least of these subjects. The scholars elected will be expected to read for honours in biology in the School of Natural Science. Candidates who are already matriculated members of the University must have passed Responsions, or the equivalent examination of the Oxford and Cambridge Schools Examination Board.

A growing feeling of the need of hospital accommodation more proportionate to the size of the town of Wakefield than that which has hitherto been supplied by the Clayton Hospital and Wakefield General Dispensary has culminated in the passing of a resolution, at the annual meeting last week of the friends of the institution, to secure a site which has just offered whereon to erect a new building. The idea seems to have awakened considerable enthusiasm amongst the more wealthy residents of the town, and £1500 was raised towards its realisation before the meeting broke up.

The death of Dr. Peter Mere Latham is announced, at the advanced age of eighty-seven. The deceased was Physician Extraordinary to the Queen, and formerly one of the physicians to St. Bartholomew's Hospital. He was a son of Dr. John Latham, a former president of the Royal College of Physicians, and also physician to St. Bartholomew's Hospital. Dr. Latham graduated at Oxford, and took his M.D. degree in 1809. He was elected a Fellow of the Royal College of Physicians in 1818, and has filled most of the offices in that institution.

Dr. Inglis has formally resigned his office as one of the honorary physicians of the Worcester Infirmary in consequence of being censured by the executive committee for on one occasion not getting a colleague to see his outpatients when he himself was called to the country, but leaving them to be seen by the resident house-surgeon. If this action of the executive committee is not disavowed by the general body of governors, so much the worse for the future of Worcester Infirmary.

The Vestry of Kensington at their last meeting, by a unanimous vote, raised the salary of their medical officer of health, Dr. Dudfield, from £300 to £400 per annum, with expressions of approval of that gentleman's services, creditable to themselves, and which must have been peculiarly gratifying to their officer.

The following appears in the *Glasgow Herald* of July 26th. As this is the first occasion for many years on which Glasgow University has recognised an extra-mural lecturer, it seems worthy of insertion. "The Glasgow University Court have agreed to recognise, as qualifying for graduation in the University, the course of lectures on Systematic Surgery to be delivered by Dr. Hector C. Cameron in the Glasgow Royal Infirmary."

The prevalence of scarlet fever in Warrington has induced a member of the Town Council to urge upon his colleagues the necessity of erecting in the borough a hospital for the reception and treatment of infectious diseases. Alderman Burgess, in advocating the adoption of this course, stated that one medical man in the town had under his professional care no fewer than twenty-five patients suffering from scarlet fever.

We understand that the Town Council of Liverpool have decided to erect a cholera hospital in the Mersey, and have applied to the Local Government Board for authority to borrow £15,000 for the purpose. Last week Colonel Cox held an inquiry in the town on behalf of the authorities at Gwydyr House, when evidence demonstrating the necessity of such an institution was given.

The medical officer of health for Wolverhampton, Mr. J. H. Love, in his annual report of the condition of the town during the past quarter, states that puerperal fever was very prevalent in the period. The death-rate of children under five years of age was high, and the mortality from chest affections seems to have been above the average.

Cholera appears to be increasing at an alarming rate in Syria. The latest weekly return approximately gives the number of persons attacked in that period as 500, a large proportion of whom died.

The bust of Dr. Hughes Bennett, by Mr. W. Brodie, will be presented to the Senatus of the University of Edinburgh by Dr. Andrew Clark, on behalf of the subscribers, on Monday, August 2nd, after the graduation ceremony.

Correspondence.

"Audi alteram partem."

PUERPERAL FEVER.

To the Editor of The Lancet.

Sir,—In your leader of the 24th inst. on the late discussion on Puerperal Fever you made a practical and, I think, most useful suggestion—"That this discussion should be supplemented by the record of carefully investigated local epidemics or series of cases, or even *isolated cases*, arising under circumstances that admit of precise analysis and estimation in their bearing on cause, nature, and treatment." You even infer the weak point of the debate was the want of practical experience of the speakers, and regret that more general practitioners did not take part in the discussion, and respond to Mr. Wells's invitation and desire which he expressed in his opening remarks, when he said his object was "even to elicit rather than to impart information; to call forth the stores of knowledge now latent in the Society; to ask for the result of observation." The following facts it was my intention to have communicated to the Society on the last night of the debate, and my name was given as one of the intended speakers. An urgent professional engagement frustrated my intention. In response to your suggestion I send you the following brief notes of two cases of puerperal fever occurring in my practice in 1870 and 1871. The first case bears on Dr. Hicks's statement, who said:—"My observations have gone to show that in certain cases there is no rash, and that there are none of the prominent symptoms of scarlatina, in cases of puerperal fever where scarlatina has been unquestionably mixed up." The second case proves beyond all doubt the nurse was the origin of infection, and shows the connexion between erysipelas and puerperal fever, and again confirms what is now, I believe, a universally accepted fact—the danger and liability of conveying puerperal fever if exposed to, or suffering from, erysipelas. A friend of mine, a hospital surgeon, told me his father died from erysipelas shortly after having attended two fatal cases of puerperal fever which had caused him very considerable anxiety.

On Monday, June 27th, 1870, I was sent for to attend Mrs. D——, aged thirty-one, in her fourth labour. On my arrival I found the child born; the labour had been both quick and easy, but the placenta was slightly adherent. She progressed satisfactorily up to the fourth day, when she complained of pain under the heart and distressed breathing, and expectorated a little red-coloured sputa. The abdomen was not at all tender, and no fever. She had a small thready pulse, and suffered intensely from thirst. The symptoms gradually increased in severity, especially the distressed breathing, which amounted the last day or two to violent attacks of orthopnœa. She died on Sunday, July 3rd, the seventh day of her confinement. The leading symptoms were great difficulty of breathing, anxious countenance, intense thirst, small, feeble pulse, acute pain under the left nipple, violent palpitation of heart, slight distension *but no pain of abdomen.* She had a little cough and a little phlegm, which was once or twice slightly tinged brown. This case occurred in a school. Scarlatina had been in the house off and on for months. Her little boy was ill at the time she was confined, and died on the 18th of July, from scarlatina maligna, the twenty-fourth day of illness. On July 2nd (the day before Mrs. D—— died) I attended Mrs. G—— in her fifth labour, which was more tedious and painful than usual. On the second day she had scarlatina anginosa, and on the twenty-second acute rheumatism. The attack of scarlatina was rather severe, the rheumatic fever very so. The former in no way differed from the usual course; the rash was bright scarlet, and was followed by free desquamation. The throat was troublesome the first week. She had one or two alarming attacks of syncope while suffering from rheumatic fever, and auscultation discovered cardiac murmurs; but these were functional, as they disappeared as convalescence was established. Her recovery was delayed for two or three months. I have since attended her in three labours, which were natural, and she made a good and early recovery from each. I would add I certified in good faith that Mrs. D—— died from pleuro-pneumonia, pericaditis, four days, seven days after a natural labour. Subsequent painful experience has left not a doubt in my mind that the case was one of true malignant puerperal fever, and that scarlatina, being in the house, was the probable cause. I attended several other women during the same time, without a bad symptom, excepting Mrs. G——, who contracted scarlatina, probably, I fear, conveyed by myself from Mrs. D—— or her child, the latter at that very time ill with scarlatina of malignant type. Mrs. G——'s baby and all her children (three in number) caught the disease, but not until after the rash had appeared for some days on my lying-in patient; the baby and also one other child dying after a few days' illness. The eldest child recovered. For some time I believed, what I tried to convince the mother, that although the disease showed itself first in her, yet it was her children from whom she caught the disease; the scarlatina poison was first in their blood, and it was the peculiar condition pertaining to the puerperal state that caused the rash to appear first in herself. I ought also to mention that Mrs. D—— was seen by two other medical men, who diagnosed her case as one of low typhoid, and *not* puerperal fever, and neither did I think it was until some months afterwards.

On Monday, about 2 A.M., Feb. 13th, 1871, I was summoned to attend Mrs. S—— in her third labour. On my arrival I found the child born, and the nurse exultingly showed me the placenta in chamber, saying at the same time, "You need not have brought your newspaper, as all your work is done for you." I found the pulse good, uterus contracted. I bandaged her and returned home in about half an hour. I had not attended any case of puerperal fever that year, nor was I attending at that time any infectious case. Mrs. S—— progressed satisfactorily until the third day, when the disease was ushered in with a severe convulsion, and she died on the eleventh day, Feb. 23rd, 1871, from puerperal peritonitis. The prominent symptoms were, an attack of convulsions lasting about an hour, on the third day; great pain in the uterus, which was enlarged and very dull on percussion; retching and vomiting of at first green, and latterly coffee-ground-like matter; countenance pinched and anxious; lost all interest in baby; milk arrested; lochia natural and not offensive; pulse was quick, but until the last two days not thready, as in other case; the respirations were short and hurried, latterly very quick. She complained of less acute but more continued pain as death approached, and was conscious almost to the last. There was not much fever; temperature never exceeded 100°. The nurse who delivered this woman was taken ill after the first week, and had to go home and was attended by the parish doctor, Mr. Spurgin, who kindly wrote to me stating that he had attended Mrs. C——, the nurse who delivered my patient who died from puerperal fever, and that she (the nurse) died from erysipelas on Feb. 28th, five days after the death of the woman she had delivered, and whose death was caused by puerperal peritonitis. Mr. Spurgin, in his letter to me, states that he attended Mrs. C—— from Feb. 24th till her death on the 28th. I was also consulted a short time afterwards by a poor woman who was suffering from phlegmonous erysipelas of arm and hand, and who said she thought she had poisoned her hand through washing the linen and diapers of the poor woman I attended who died in her confinement.

It has fallen to my lot to have seen several cases of puerperal fever, and in almost all I have at some trouble investigated the probable cause of infection, and the result of my experience, observation, and thought is that puerperal fever is in nine cases out of ten of zymotic origin, and that each case may be regarded as one of blood-poisoning, and the only treatment that appears successful confirms this conclusion. To quote the words of Mr. Graily Hewitt, I believe, "It it impossible to escape the conclusion that puerperal fever consists in nothing more or less than an injection into the general circulating fluid of a poisonous material of animal origin, that it is a form of pyæmia, for the production of which the minutest portion of the morbific agent may prove sufficient." But I am also led to think that there are two forms of this so-called fever, which Dr. Barnes aptly terms "heterogenetic" and "autogenetic," and that one may be more contagious than the other. "The former arises from causes outside the patient's body; the poison *has been carried to her and has been put in her.* The latter autogenetic, in which all the conditions of the fever exist or arise in the patient's system, with which infection or contagion has nothing to do."

Apologising for the length of my communication,

I am, Sir, yours truly,

Fredk. H. Alderson.

Southerton House, Hammersmith,
July 26th, 1875.

THE HEALTH OF THE TROOPS AT THE AUTUMN MANŒUVRES.

(From our Special Correspondent.)

With the face of the heavens the type of prevailing disease must change. Accordingly, while during the manœuvres of 1874 so much care was needed to protect the men from undue exposure to, or exertion in, the heat of the day, and the wildest rumours were circulated of the ravages of sunstroke, on this occasion not a single man was incapacitated from the effects of the sun, but in its stead the various kinds of rheumatism took precedence. Catarrhs and affections of the chest, such unfailing visitants of the inhabitants of houses in wet weather, are comparative strangers in the equable temperature enjoyed by the dwellers in tents. The proportion of diarrhœa amounted to about one-sixth of the total cases sent from the field.

Another condition also which has always existed on the manœuvres, and which, though productive of no very marked consequences in so short a time, still, on a campaign, would most seriously multiply the non-effectives, is want of sufficient means of personal cleanliness. No very great ingenuity would be required to devise a little india-rubber basin which, when not in use, would serve as a waterproof cover to some of the soldier's equipment, and which would well repay the few ounces' additional weight imposed, and the small expenditure incurred. Probably nothing would do more towards lessening the gaps in the ranks from foot-soreness than this.

The battles were somewhat prolific in accidents, but that may only testify to the brilliancy of the movements. On the whole, the physical condition of the men was improved by their rough field experiences.

BIRMINGHAM.

(*From our own Correspondent.*)

THE Town Council have rarely done so much important business at any one sitting as they did yesterday. They received from the Mayor, to whom great credit is due for the energy and ability with which he has prosecuted these reforms, the announcement that the Gas and Water Bills had passed both Houses of Parliament, and they appointed committees to conduct and manage these undertakings. They resolved on the adoption of the Artisans' Dwellings Act, 1875, and appointed a committee to receive official representations of the unhealthiness of any area or areas in the borough, and to submit to the Council a draft scheme for the improvement of such areas, and generally to carry out the provisions of the Act; and, lastly, they raised the salary of Dr. Hill from £650 to £1000 on consideration of his giving up the whole of his time to the duties of medical officer of health and borough analyst. No higher functions could be exercised by any corporation than the acquisition of the water supply, the improvement of the dwellings of the working-classes, and the recognition of the value of the services of a health officer.

The last report of the Birmingham Medical Benevolent Society shows that the directors had been enabled to distribute during the past year £417 to fourteen recipients, and to invest £200, and that the total property of the Society amounts to £8387. Dr. Agar, of Henley, has been elected president for the ensuing year.

The post of surgeon to the Warneford Hospital, Leamington, is vacant by the resignation of Mr. Jones. The appointment of Mr. Joseph Morris, a former house-surgeon, who at the last election in 1871 was very nearly at the top of the poll, is almost a certainty.

The report of Dr. Robinson, the vaccination officer of the parish of Birmingham, shows that 95 per cent. of the children born in the parish are accounted for by the vaccination officer, recommends that the magistrates should exercise their full powers against those who try to evade the Vaccination Act, and says that the arrangements which the guardians have made for ensuring vaccination are all that can be desired.

The committee of the Women's Hospital have for the second time appointed a lady house-surgeon. Miss Edith Pechey has been educated at the University of Edinburgh, and brings with her exceptionally good credentials.

Birmingham, July 28th, 1875.

MANCHESTER.

(*From our own Correspondent.*)

AT the Royal Infirmary, the subject which perhaps principally occupies the attention of both the medical and lay bodies just now is the contemplated removal of that institution to a more suburban position. It is rumoured that twenty pounds per yard has already been offered for land in the immediate vicinity of the present hospital, for the purpose of erecting thereon a building which shall serve for an accident department. The neighbourhood of Oxford-street, near the new Owens College, is talked of as the probable situation of the new hospital. Amongst other interesting operations performed at the infirmary lately was one for strangulated umbilical hernia, performed by Mr. Bowring. The bowel had been strangulated for several days before operation, and as a consequence required most careful dissection. Stercoraceous vomiting occurred several times at intervals of a week. This finally ceased, and the woman made a perfect recovery. Mr. Whitehead has also had a case of strangulated hernia, where the operation was complicated with troublesome and dangerous hæmorrhage from a vessel within the fold of the peritoneum, covering the bowel at its junction with the mesentery. The vessel was ultimately secured by a catgut ligature, and the patient quickly made a good recovery. Mr. Bradley continues to obtain excellent results from his plan of injecting strumous glands with the tincture of iodine, which I hope he will soon publish in detail in the pages of THE LANCET.

A successful case of ovariotomy has recently occurred at St. Mary's Hospital. The patient was about twenty-one years of age. The abdomen was intensely and universally fluctuant, with general dulness and resonant flanks. The operation was performed by Dr. Lloyd Roberts. The cyst was exposed, tapped, and drawn through the wound. There was an adhesion of a piece of omentum about 3 in. or 4 in. broad to the cyst wall; this was secured by a silk ligature, and dropped with the divided pedicle into the abdominal cavity. The woman was convalescent on the ninth day, and was discharged from the hospital on the 17th inst.

Abdominal section has also been recently performed at this hospital by Mr. Cullingworth for extra-uterine gestation. The cyst was carefully exposed, opened, and a four months' fœtus extracted. The divided edges of the cyst were included in the ligatures which secured the abdominal wound. The patient appeared to go on favourably for a few days, but, unfortunately, symptoms of broncho-pneumonia came on, and she died about the eighth day after operation.

Manchester, July 26th, 1875.

Obituary.

SIR CHARLES LOCOCK, BART.

BY the death of Sir Charles Locock our profession loses one who was for long one of the most distinguished of its metropolitan members. He occupied, thirty years ago, the highest place as a practitioner of a branch of medicine which had not then perhaps received all the honour that was its meed; and that it now obtains due estimation is in part owing to his direct and indirect influence. He was the son of Mr. Henry Locock, of Northampton. A year older than the century, he graduated at Edinburgh in 1821, and soon afterwards commenced practice in London as an obstetrician. His success was rapid. Midwifery is a department of practice in which success often comes earlier than in most other branches. The demand which it makes on the physical powers throws its active work in the hands of comparatively young men. Still, the rapidity with which Sir Charles Locock made his way in fashionable practice was remarkable. At an age when most London physicians have hardly made good their first step, he had attained the highest position open to him, in being selected, by the advice of Sir James Clark, at the age of forty, as the Queen's physician-accoucheur—a post which he held up to the time of his death, and discharged its active duties as often as the occasion for his services arose. He was created a baronet on his retirement from practice nearly twenty years ago, a retirement which has also extended to all parts of public professional life. He was elected Fellow of the Royal Society in 1864, and in 1865 was an unsuccessful candidate for the representation in Parliament of the Isle of Wight.

During his career in town his practice was a very large one, perhaps the largest ever made by an obstetric physician. He owed it in part to his personal qualities, but chiefly to his remarkable practical knowledge and skill, which made his contemporary reputation as high with the profession as with the public. He wrote but little; his only published work was his inaugural thesis, "De Palpitatione Cordis," on obtaining his degree in 1821. He contributed articles on menstrual disorders, diseases of lactation, and infantile and puerperal convulsions, to the "Cyclopædia of Practical Medicine."

The late Sir Charles Locock possessed many attractive social qualities. He was fond of society, and made warm friends among all with whom he was brought into contact, foremost among whom must be mentioned Her Majesty, whose high regard for his personal character and professional ability is well known. To most of the younger generation of the profession he has been known only by name, but to a large number of its older members pleasant recollections of former professional intercourse will cause the news of his death to come with regret.

Sir Charles Locock has left several children, some of whom occupy honourable positions at the bar, in the church, and in diplomacy. His wife died in the year 1867.

ALEXANDER M. OFFICER, M.D.

DR. OFFICER was born at Stonehaven, Kincardineshire, on April 21st, 1820, and, prior to entering College at Aberdeen, was a private pupil of the late Dr. Pratt, of the Episcopal Church, Cruden, author of "Buchan" and other works. He was articled to Dr. David Kerr, Aberdeen, and took his degree of M.D. in 1843. He afterwards became a partner with, and latterly succeeded to, the late Dr. James, of Brechin, where he remained nine years. He then removed to Montrose, where, in addition to a select general practice, he held the offices of assistant-surgeon to the Forfar and Kincardine Militia Artillery, Admiralty surgeon and agent, medical attendant to Dorward's House of Refuge, and medical officer to the Royal Infirmary. In all these capacities he enjoyed the confidence and respect of those with whom he came in contact. He was one of the most unselfish of men, and counted neither trouble nor cost in going out of his way to visit the sick or to do a kind act, whether pecuniary or otherwise.

It was in the course of his professional avocations at Montrose that he came by two accidents which brought on his last sad illness. The first was being thrown from his horse near a railway, at which the animal took fright, and the other was a puncture in one of his fingers while operating upon a patient in the Montrose Infirmary. The latter was very serious, though not immediately; but the severe treatment to which he subjected himself weakened his physical and mental powers to such a degree that he retired to his native place, where he died, after a lapse of two years, of softening of the brain and general paralysis on the 24th of April.

BECKIT TRUMAN, M.R.C.S. ENG.

MR. TRUMAN was born in June, 1802, at Bulwellwood Hall, Notts, the residence of his forefathers for 250 years. He studied at Guy's and St. Thomas's whilst they were united, and was a favourite pupil of Sir Astley Cooper, who spoke in high terms of his industry and knowledge. Having obtained the L.S.A. Lond. in 1825, and the M.R.C.S. Eng. in 1826, he settled in Nottingham and acquired an extensive practice, until in 1860 the demands on his time and strength were incessant. It was at this juncture, when the powers of life were becoming feebler, and no rest was possible, that his finger was inoculated with syphilitic virus from an obstetric case. The consequences were very sad, and were never recovered from, leading ultimately to his death fifteen years after.

Mr. Truman was a man universally respected, and his deep and unfeigned belief and trust in the truths of revealed religion were the causes of unfailing patience and goodness. A proverb says, "Ubi tres medici, duo athei"; but Mr. Truman could, whilst hearing and seeing the facts that are alleged by materialists to prove their theories, fearlessly and simply receive as true the lessons taught him from his mother's bible: he received them as a little child, never doubting.

Mr. Truman married early in life Susanna Mary, daughter of Mr. Joseph Smith, of Trent Bridges, Nottingham, who predeceased him by six months. Eleven sons and daughters, all grown up, remain to mourn his loss.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. — The following gentlemen, having passed the required examinations for the diploma, were duly admitted Members of the College at meetings of the Court of Examiners on the 22nd, 23rd, 26th, 27th, and 28th inst.:—

Baker, Alfred De Winter, Dawlish.
Barker, Walter Herbert, Brighton.
Bartlett, Henry, L.S.A., Great Dover-street.
Bowen, Alfred L., Ludlow.
Brenchley, Algernon D., L.S.A., Denmark-hill.
Briggs, Harry B., L.S.A., Horncastle.
Brooks, Walter John, Westminster-bridge-road.
Brown, Thomas Lloyd, Camberwell.
Bruce, Peter, L.S.A., Valparaiso.
Burton, Edward Campbell, Lee.
Burton, James K., Doughty-street.
Burtonshaw, Thomas, L.S.A., Hackney-road.
Carter, Frederick H., Pewsey.
Cock, William, Redruth.
Colborn, Henry, Wimbledon.
Collins, Henry A., L.S.A., Bayswater.
Collyns, Robert T. P., Gower-street.
Continho, Joaquim V., Goa, Bombay.
Cooke, William Conway, Brompton, Kent.
Coom, Richard, Bodmin.
Couldrey, James, L.S.A., Abingdon.
Cory, Frederick W., L.S.A., Buckhurst-hill.
Crocker, Henry Lawrence, Plymouth.
Curwen, Cecil, Worlington.
Cundell, George R., L.S.A., Lock Hospital.
Davies, Thomas, Barmouth.
Dickinson, William Gilbert, Hampstead.
Druitt, Lionel, Strathmore-gardens.
Farfan, Joseph V., Claverton-street, Pimlico.
Fisk, George H. B., Camden-square.
Godfrey, Robert F., M.D., Montreal.
Grasett, Frederick Le Maitre, M.B. Edin., Toronto.
Greenish, Robert William, New-street.
Ground, Edward, Whittlesea.
Hancock, Charles J., Bath.
Hancock, John Gatchell, Halse, near Taunton.
Harvey, Frederick G., Spalding.
Harrison, Edwin, Wrexham, Denbigh.
Hattie, Alexander G., M.D., Antigua, West Indies.
Hay, William A. E., L.S.A., Bridport.
Henley, Edward W., Derby.
Hind, Henry Joseph, L.S.A., Twickenham.
Hopkins, John, Northwich.
Hovell, Thomas M., Clapton.
Humphry, Reginald, Kensington.
Jameson, George H., M.B. Edin., Heywood, near Bury.
Johnston, Chadd M., Lancaster.
Jones, Benjamin, Chorley.
Karop, George C., L.S.A., Camden-town.
Lacy, Alexander G., L.S.A., Guernsey.
Lancaster, Henry Francis, Amersham-park-villas.
Langley, John G., Mildmay-grove.
Leeson, John Rudd, Teddington.
Le Quesne, Edwin J., Jersey.
Lucas, Arthur, L.S.A., Barwell, Cambridgeshire.
Makins, George H., L.S.A., Walton-on-Thames.
Mason, John W. B., Osnaburgh-terrace.
Morgan, David Craven, Llanddewi Brefi, South Wales.
Mugliston, Thomas Crichton, Plymouth.
Needham, Joseph, Victoria-park.
Newland, Charles Francis, Bradleigh, Down.
Noot, Henry Curtis, Dudley.
Phillips, James Alfred, Guildford.
Pettigrew, Augustus J. W., Hounslow.
Rees, Charles, L.S.A., Cape Town.
Richardson, Joseph B., L.S.A., Castle Bytham.
Roughton, Walter, Hammersmith.
Routh, Alfred Curtis, Meyrick-square.
Sangster, Alfred, M.B. Cantab., Streatham-hill.
Scott, Alexander Thomas, L.S.A., Cantlows-road.
Shadwell, St. Clair B., Walthamstow.
Sibbering, George, Merthyr Tydfil.
Stevenson, Robert A., M.D. M'Gill Coll., London, Ontario.
Sworder, Horace, Luton, Bedfordshire.
Symonds, Edmond, Thaxted, Essex.
Tamplin, Charles H., Old Burlington-street.
Taylor, Henry Cumberland, L.S.A., Trinity-square.
Todd, John, Tufnell-park.
Traill, Mark Windeyer, Kinross.
Turnour, Charles C., Millman-street.
Vernon, Mark H. H., Battle, Sussex.
Wakefield, Thomas, Nottingham-place.
Ward, Austin George, Carlton-hill.
Willis, Charles Fancourt, Penton Hook.
Wilding, Leonard James, Worcester.
Williams, Neville, Ruthin, Denbigh.
Woollett, Charles Jerome, Monmouth.

Of the 175 candidates examined during the last and present weeks, 113 satisfied the Court of Examiners and obtained their diplomas; 15 candidates passed the examination in Surgery, and, when qualified in Medicine, will be admitted Members, and 47 were referred to their professional studies for six months.

Apothecaries' Hall. — The following gentlemen passed their examination in the Science and Practice of Medicine and received certificates to practise on July 22nd :—

Branson, John, Rotherham, Yorkshire.
Clarke, Arthur, Brill, Bucks.
Davies, John, Queen-street, Worship-street.
Eames, James Crompton, Kearsley, near Manchester.
Laverick, John Valentine, Hinderwell, Yorkshire.
Morgan, William, Ynysmudw, Swansea Valley.
Richardson, Joseph Berridge, Castle Bytham, near Stamford.

The following gentlemen passed the Primary Professional Examination on the same day :—

Robert Huntley Campbell, St. Thomas's Hospital ; Thos. Baxter Carlyon, St. Bartholomew's Hospital ; Ernest James Pritchard, Guy's Hospital ; Charles James Rayley Owen, St. Mary's Hospital.

Dr. Welsh, of Kinghorn, N.B., was recently presented by his friends and patients with a purse of money and a very handsome marble timepiece.

At the Bath Town Council meeting a short time back, it was resolved to purchase, for £8100, a site on Claverton Down for an asylum for pauper lunatics.

The Quarterly Court of the directors of the Society for Relief of Widows and Orphans of Medical Men was held in the rooms of the Royal Medical and Chirurgical Society, 53, Berners-street, on the evening of July 14th, Mr. Charles Hawkins, vice-president, in the chair. The sum of £1116 10s. was voted to be distributed among fifty-seven widows now receiving grants, a sum of £75 10s. to be divided between seventeen children, and a further sum of £19 10s. was granted to three children from the Copeland Fund. The expenses of the quarter amounted to £66 10s.

Bequests, &c., to Medical Charities.— Mr. Selwood Riddle has this week presented to the Bristol Royal Infirmary the munificent donation of £3000. Mr. Joseph F. Duckett, of Kingstown, bequeathed £500 each to the Adelaide Hospital, Mercer's Hospital, Steeven's Hospital, Meath Hospital and County Dublin Infirmary, and Sir Patrick Dun's Hospital, all at Dublin. The Worcester Infirmary has become entitled to £300, 4 per cent. Debenture Stock London and North Western Railway Company, under the will of Miss Harriet Watkins, of Ombersley.

Medical Appointments.

Allchin, W. H., M.B., M.R.C.P., has been appointed an Assistant-Physician to the Victoria Hospital for Children.

Baly, J. S., M.R.C.S.E., has been reappointed Medical Officer of Health for the Leamington Urban Sanitary District, at the increased salary of £80 per annum.

Bredin, J. N., L.R.C.S.I., has been appointed Medical Officer and Public Vaccinator for the Sutton District of the Hollingbourn Union, Kent, vice Sankey, resigned.

Browne, T. H., L.K.Q.C.P.I., L.M., L.R.C.S.I., has been appointed Medical Attendant to the Royal Irish Constabulary, Frankford, King's County, vice Ridley, resigned.

Clark, W. W., M.D., M.R.C.S.E., has been appointed Medical Officer for the Wellingborough District and the Workhouse of the Wellingborough Union, vice T. Clark, F.R.C.S.E., resigned.

Cosgrave, A., M.R.C.S.E., has been appointed Junior House-Surgeon to the Royal Infirmary and Dispensary, Manchester, vice Byrne, whose appointment has expired.

Deane, J., M.D., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Warboys District of the St. Ives Union, Hunts, vice Serjeant, resigned.

Dobie, W. M., M.D., M.R.C.S.E., has been appointed a Physician to the Chester General Infirmary, vice Waters, resigned.

Griffiths, D., M.B., C.M., has been appointed Medical Officer and Public Vaccinator for the Llandilo-Talybont District of the Swansea Union, vice Jones, resigned.

Harvey, R. J., M.D., has been appointed Assistant-Physician to the Richmond, Whitworth, and Hardwicke (House of Industry) Government Hospitals, Dublin, vice Yeo, appointed Professor of Physiology at King's College, London.

Hill, T., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Chipping-Warden District of the Banbury Union, Oxfordshire, vice Fowke.

Hope, J., M.D., L.R.C.S.Ed., has been appointed Medical Officer and Public Vaccinator for the No. 3, or Chobham District of the Chertsey Union, Surrey, vice Ward, resigned.

Hutchinson, V., M.D., M.R.C.S.E., has been reappointed Medical Officer of Health for the No. 3 Sub-district of the Auckland Rural Sanitary District.

Iles, D., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the first Division of No. 3 District of the Northleach Union, and Medical Officer of Health for the first Division of No. 3 Sub-district of the Northleach Rural Sanitary District.

Irvine, J. P., M.D., M.R.C.P.L., has been appointed Assistant-Physician to the Victoria Hospital for Sick Children, Queen's-road, Chelsea.

Kenyon, G. S., L.R.C.P.Ed., L.F.P. & S. Glas., has been appointed Medical Officer for the No. 4, or Tarleton District of the Ormskirk Union, vice Hilton, whose appointment has expired.

Kidd, G. H., M.D., F.R.C.S.I., has been appointed Consulting Obstetric Surgeon to the Richmond, Whitworth, and Hardwicke (House of Industry) Government Hospitals, Dublin.

Kilburn, W. B., M.R.C.S.E., L.M., has been reappointed Medical Officer of Health for the No. 2 Sub-district of the Auckland Rural Sanitary District.

M'Kane, G. O., L.R.C.P.Ed., L.M., L.F.P. & S. Glas., has been appointed Medical Officer of Health for the No. 1 Sub-district of the Auckland Rural Sanitary District, vice Manson, whose appointment has expired.

Manser, R., M.R.C.S.E., has been appointed House-Physician to the Hospital for Women, Soho-square, vice Skelly, appointed Resident Surgeon to the Western General Dispensary.

Palmer, F. S., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Mortlake District of the Richmond Union, Surrey, vice Alex. Crichton, L.R.C.P.Ed., L.R.C.S.Ed., deceased.

Phillips, S. R., M.D., C.M., has been appointed Non-resident Medical Officer to the Branch Dispensary of the Cheltenham General Hospital and Dispensary.

Robertson, J., L.R.C.S.Ed., has been appointed Medical Officer and Public Vaccinator, and Medical Officer of Health, for the Parish of Fordoun, Kincardineshire, vice Henderson, deceased.

Sellers, W., M.R.C.S.E., has been appointed Medical Officer for the Radcliffe District of the Bury Union, vice Bott, resigned.

Seward, W. J., M.R.C.S.E., has been appointed Assistant House-Surgeon to the Bristol General Hospital, vice Thornley, appointed Assistant Medical Officer to the Leicestershire and Rutlandshire Lunatic Asylum.

Smith, C. E., M.R.C.S.E., L.R.C.P.L., has been appointed Senior House-Surgeon to the Royal Infirmary, Manchester, vice Birch, resigned.

Waters, E., M.D., F.R.C.P.Ed., F.K.Q.C.P.I., has been appointed Consulting Physician to the Chester General Infirmary, upon resigning as Physician.

Woods, G. A., L.R.C.P.Ed., L.M., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the No. 2, or North Meols District of the Ormskirk Union, vice G. Woods, F.R.C.S.E., resigned.

Woods, O. T., M.D., L.R.C.S.I., Senior Assistant at the Warwick County Asylum, has been appointed Medical Superintendent of the Killarney District Asylum, vice Murphy, deceased.

Wreford, S., M.R.C.S.E., has been appointed House-Surgeon to the York County Hospital, vice Kebbell, appointed Medical Officer to No. 4 District, York Union.

Wright, J. B., M.D., M.R.C.S.E., has been appointed Medical Officer for the Finedon District of the Wellingborough Union, vice Clark, resigned.

Births, Marriages, and Deaths.

BIRTHS.

Child.—On the 26th inst., at New Malden, Surrey, the wife of Edwin Child M.R.C.S.E., of a son.

Dudgeon.—On the 23rd inst., at Montagu-square, the wife of R. E. Dudgeon, M.D., of a daughter.

Fraser.—On the 20th inst., at Knutsford, Cheshire, the wife of Thos. R. Fraser, M.D., of a son.

Jeffery.—On the 20th inst., at Trinity House, Eastbourne, the wife of G. A. Jeffery, M.D., of a son.

Morris.—On the 15th inst. (St. Swithin's), at Euston-place, Leamington, the wife of J. Morris, Surgeon, of a son.

Theobalds.—On the 13th ult., at Jubbulpore, the wife of Surgeon-Major J. R. Theobalds, 16th Madras Native Infantry, of a daughter.

MARRIAGES.

Atkinson—Timins.—On the 28th inst., at the Parish Church, Kingston-on-Thames, Frederick P. Atkinson, M.D., of Surbiton-road (eldest son of J. C. Atkinson, M.D., of Kew-green, Surrey), to Eliza Henrietta, only daughter of A. Kier, M.D., of Tunbridge Wells, late H.E.I.C.S., and widow of the late Douglas C. Timins, M.A., of Hilfield, Aldenham, Herts.

Field—Browne.—On the 11th ult., at St. Paul's Church, Kingsey, P. of Quebec, Canada, Albert Field, M.B., C.M., of Bridge-town, Barbadoes, W.I., to Dora Caroline, eldest daughter of G. S. H. Browne, Esq., late of the Bengal Army.

Holman—Partridge.—On the 22nd inst., at St. Philip's, Kensington, Robt. Colgate Holman, M.R.C.S.E., L.S.A.L., of Keighley, Yorkshire (youngest son of Henry Holman, Esq., of East Hothly, Sussex), to Edith Sybilla, daughter of the late Samuel John Partridge, Barrister-at-law, of Kensington, and Stroud, Gloucestershire.

Norbury—Fitzgerald.—On the 21st inst., at the Parish Church, Prestbury, Cheshire, Thos. Wm. Norbury, of Crediton, North Devon (second son of the late Thos. Norbury, Esq., of Upton Hall), to Eliza Theresa, daughter of Captain T. C. Fitzgerald, of Upton Grange, Macclesfield, Cheshire.

DEATHS.

Betts.—On the 20th inst., at Bonchurch, Isle of Wight, Geo. Harvey Betts, M.D., aged 66.

Burt.—On the 18th inst., at Edinburgh, Benj. Burt, M.D., aged 78.

Clarke.—On the 25th inst., at Cambridge, Wm. J. Clarke, M.R.C.S.E., of Huddersfield, aged 61.

Davidson.—On the 26th inst., at Heathcote-street, Mecklenburgh-square, C. J. Davidson, late Surgeon 47th Bengal Native Infantry, aged 64.

Lovell.—On the 19th inst., at Sandymount, John Lovell, M.R.C.S.E., Inspector-General of Hospitals, formerly of the Madras Medical Service, aged 71.

Moffatt.—On the 31st of May, at Naini Tal, India, Elizabeth Abbott, the beloved wife of Surgeon-Major J. E. Moffatt, 1–14th Regiment.

Robertson.—On the 20th ult., at sea, on the passage to Jamaica, Schoedde Robertson, M.D., Staff Surgeon Army.

Thomas.—On the 19th inst., Richard Thomas, L.R.C.P.Ed., of Mold.

Todd.—On the 6th inst., at Honley, Yorkshire, J. Todd, L.F.P. & S. Glas., aged 29.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*]

Notes, Short Comments, and Answers to Correspondents.

ESERINE IN CHOREA.

M. BOUCHUT has been experimenting with this alkaloid on children, and states (in the *Bull de Thérap.*, April 15th, 1875), among other things, that it may be ingested in the stomach or used hypodermically. The sulphate may be injected in doses of the tenth or the eighth of a grain; the dose should be larger when taken into the stomach. The effect of injections is very energetic, and in both cases the alkaloid should be administered fasting. The action lasts from one to three hours, and then entirely disappears, so that from three- to four-tenths of a grain may be used in three doses in the course of the day. This action with children is observed in a few minutes. The little patients may turn rather pale; but with the doses mentioned nothing serious has occurred. By injecting the tenth of a grain, the diaphragm is found to be partially paralysed. When eserine is used in chorea, it arrests the convulsive movements whilst its action lasts, and, by its continuous use, gradually moderates them. A cure may be obtained in about ten days. For this purpose we should inject a twelfth of a grain under the skin, or give a sixth by the mouth. It is, however, important to repeat the doses as soon as the usual eseric effects have disappeared, and it should be observed that the cessation of the choreic movements persists only whilst the alkaloid is being eliminated. M. Delamarre has tried hypodermic injections of eserine in two cases of traumatic tetanus. The patients died; but great improvement was obtained after each injection, so that new trials may be expected to lead to more favourable results.

Enquirer should address a note to Mr. Frank Buckland, of *Land and Water*.

THE EXAMINATION FOR THE ARMY MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—It has been generally believed for some months that a new Warrant most favourable to the army medical service is about to appear, and no doubt the expectation of it will induce many young medical men to present themselves at the approaching examination in August. To these I would tender *Punch's* well-known advice, "Don't." Be it remembered, the same tactics were tried in 1864, when it was generally believed that a new and favourable Warrant was actually in print; but as soon as the requisite number of candidates was obtained the document was thrown into the waste-paper basket. Mr. Hardy's reply to Dr. Lush's motion is certainly far from satisfactory. I would refer intending candidates to last week's *Broad Arrow;* and if, after perusing the excellent article therein, they still venture to come up for the examination, they have only hereafter to blame themselves.

By the way, the last insult offered to the medical profession is the insertion of an authority into the commissions of captains and lieutenants of orderlies to *command* medical officers who may be junior to themselves, thus raising up an *imperium in imperio*, which must prove utterly destructive to all good feeling between medical officers and their *quasi* medico-purveyor-combatant anomalies, yclept captains of orderlies; and, to make matters worse, the heads of the medical department, under whose orders these hospital stewards (as they ought to be called) are really placed, have no power of command over their own subordinates.

At the present moment the position of affairs is this: A surgeon-general in charge of a hospital—say the Herbert at Woolwich—has no power to give a private orderly a pass, but can direct the captain of orderlies to do so, who has perfect power to refuse it or not as he pleases, subject, of course, to his conduct being investigated afterwards.

With the abundant warning before them, if young medical men persist in taking service before matters are put to rights, they have hereafter their own folly only to blame, and they cannot say the medical officers of the army have not given them ample warning.

Yours obediently,

July 26th, 1875. AN ARMY SURGEON.

To the Editor of THE LANCET.

SIR,—Mr. Gathorne Hardy's reply to Dr. Lush's motion in the House of Commons on Friday last being vague and unsatisfactory to a degree, holding out no hope that one single grievance under which army surgeons are now suffering will be ameliorated—viz., stagnation of promotion, loss of forage, dismissal from their regiments without compensation, compulsory payment of entrance fees and subscriptions to mess and band funds of regiments to which they are only *attached*, difficulty of getting leave, refusal of exchanges, with many others which have been fully discussed in your columns,—I therefore write to entreat my young medical brethren who are thinking of entering the army to pause ere they do so, and to assure them that their position and prospects in the Royal navy or Indian medical services are infinitely superior to the Royal army, in which for years we have been suffering from injustice and broken faith. I write these words with deep regret. Twelve years ago I was full of *esprit de corps*, proud of my commission, proud of being an army surgeon. Now all that is changed, and, in common with a large majority of my brother officers, I look forward eagerly to the day in which I may resign a commission the acceptance of which was a mistake.

Yours obediently,

AN ARMY SURGEON OF FOURTEEN YEARS' SERVICE.

July, 1875.

POOR-LAW RELIEF.

Fair Play.—A parish medical officer argues the propriety of relieving officers granting relief only on the certificate of the parish surgeon. This, we presume, is the legal course, and, on the whole, is the reasonable one. In his union he complains that relief is granted on the certificate of another irresponsible practitioner as readily as on his own.

WE have received a communication from *Mr. Clarke*, of Lincoln, in reference to his blood mixture, which we hope to insert next week.

SUSCEPTIBILITY TO PAIN IN THE LOWER ANIMALS.

MR. GEORGE PORRITT, curator of the Huddersfield Naturalists' Society Museum, in a lecture lately delivered before the Society, narrated a circumstance recorded by Coleman, which is calculated to soothe one's sensibilities in view of the enormous aggregate amount of inevitable pain suffered by the lower animals in their often brief life history. "I have seen," says Coleman, "a wasp, that has been snipped in two, afterwards regale himself with avidity upon some red syrup, which, as he imbibed, gathered into a large ruby head just behind the wings, where the stomach should have been; but really the creature's pleasures seemed only to be augmented by the change of his anatomy, for he could take ten times his ordinary fill of sweets, without, of course, getting any the fuller."

Angina Pectoris.—The subject will be found treated in most works on Medicine: Watson, Aitken, or Roberts.

Nemo, (Glasgow.)—Has our correspondent tried belladonna for checking night-sweats?

ERYSIPELAS DURING PARTURITION.

To the Editor of THE LANCET.

SIR,—I was called in to see Mrs. G——, aged twenty-two, pluripara, a strong, healthy young woman, who hourly expected to be confined. I found her suffering from a severe attack of erysipelas, affecting chiefly the face, throat, and fauces, accompanied with great constitutional disturbance. Ordered castor oil, six drachms, immediately, to be followed after the bowels were relieved by tincture of perchloride of iron, twenty minims; solution of acetate of ammonia, two drachms; water to one ounce; the face to be dredged with flour; steam inhalations for the throat. Diet: milk, eggs, and beef-tea. No stimulants.

Seen next morning. The oil had acted freely; the tongue was cleaner; she had frequent rigors from the commencement of her illness. I was sent for at 4 P.M. on the same day, as she was in labour. On making a vaginal examination, I found the os dilated to the size of half-a-crown, the vertex presenting; the soft parts were very hot and swollen; the secretions scalding, acrid, pungent, and offensive. She was delivered at 6.45 P.M. of a small, weakly child, asphyxiated, but surviving on the employment of resuscitating measures. It died on the ninth day of icterus neonatorum. Having removed the placenta by Crede's method, and applied a compress and binder, I gave her liquid extract of ergot, thirty minims, to ensure if possible permanent contraction of the uterus. At 9 P.M. she had not passed urine; the after-pains were not severe; had passed a few clots, but the lochia were rather scanty, bad-coloured, and offensive; pulse 120; skin very hot and dry. Left her three pills, containing one grain of opium each, one to be taken every four hours. To continue steel mixture.

The next morning I found on inquiry that she had passed urine; she had several rigors during the night; the uterus was larger than normal, and tender on pressure; the lochia scanty and offensive; pulse 126; skin hot and pungent to the touch; erysipelas of face lessened. Ordered quinine, five grains; dilute sulphuric acid, five minims; tincture of opium, ten minims; water to one ounce: to be taken every four hours; and an antiseptic uterine injection of carbolic acid to be used warm night and morning.

The symptoms gradually improved until, on the fifth day from her delivery, I was pleased to find the erysipelas rapidly defervescing, the lochia natural, no subinvolution of the uterus, nor abdominal tenderness. She had no rigor on the previous day, and the bowels had been relieved without any aperient medicine having been exhibited. Lactation was established. The quinine and injection were discontinued, and she was ordered tincture of perchloride of iron, fifteen minims, chlorate of potass, five grains; water to one ounce: every four hours.

On the ninth day the patient was sufficiently well for me to discontinue my visits. The breasts, which had been drawn with a breast-pump, had given her no trouble. She was advised to remain in bed for another week, and to recline the greater part of the day until the end of her puerperal month; to take her medicine three times a day after meals, which were to consist of ordinary diet—tea, coffee, milk, bread, meat, and bitter ale.

She was seen again at the end of the month, when I learned that her recovery had been uninterrupted and complete.

On inquiry I ascertained that the drainage of the house was defective, and that two people living in it had suffered from sore-throat and a third from diarrhœa at about the same time as Mrs. G——'s illness. I may add that I continued my midwifery practice during my attendance on Mrs. G——, whilst using every precaution, such as change of clothes and frequently washing my hands with disinfectants, without any bad results to my patients.

I would also ask, is it possible that the speedy exhibition of quinine to chinchonism and the use of an antiseptic injection were the means of warding off in this case an impending attack of puerperal fever?

I remain, Sir, yours truly,

High-street, Deptford, July, 1875. W. R. SMITH, M.R.C.S.

A PHOTOGRAPHIC WONDER.

DR. ULTZMANN, teacher at the University of Vienna, lately read a paper before the Medical Society of Lower Austria on the "Use of Photography in Medical Studies." *Inter alia*, he mentioned, on the authority of Dr. Vogel, that an eruption of small-pox had been made evident by photography twenty-four hours *before* it actually came out. Although no one could as yet observe anything on the skin of the patient, the negative plate showed stains on the face which perfectly resembled the variolous exanthem, and twenty-four hours afterwards the eruption became clearly evident.

A. B.—We must decline to notice the matter. It is disgraceful to all parties.

SUPERANNUATION OF POOR-LAW MEDICAL OFFICERS.

To the Editor of THE LANCET.

SIR,—Can any of your readers answer me this question:—If a medical officer serves 20 years in the Poor-law service, and retires when 50 years of age, can he when he becomes 60 years of age claim a pension?

Yours &c.,

July, 1875. ENQUIRER.

Small-pox in France.

At a late meeting of the Paris Medical Society of Hospitals, M. Moissenet stated that hospital authorities had at length decided that small-pox patients should be received in special wards. Why such a measure was not taken years ago is hardly conceivable. It has also been resolved that variola wards should be set apart at Vincennes and Vésinet, which are institutions where the convalescent from the Paris hospitals are sent. Indeed *all* convalescents used to be sent to these institutions, which are situated in the immediate vicinity of Paris. Among these patients were many just recovering from small-pox; they were conveyed by rail, and the seats they had occupied were *immediately afterwards* used by the general public. Whether the authorities are wise in setting apart wards for small-pox patients in an asylum intended for convalescent patients is extremely doubtful. At all events, it is to be hoped that when variolous patients are sent thither, they will not be conveyed by rail.

Dissector.—Gray's or Quain's Anatomy; Kirkes's, Marshall's, or Carpenter's Physiology.

Mr. Wynter Blyth.—The paper shall receive attention.

A Case of Post-partum Hæmorrhage unsuccessfully treated by Injection of Tincture of Iron.

To the Editor of The Lancet.

Sir,—As we have heard so much of late about the injection of perchloride of iron in post-partum hæmorrhage, I venture to suggest that the following case is worthy of attention.

A short time back, while taking temporary duty in the absence of a medical friend, I was called to Mrs. D——, aged forty, who was taken in her twelfth confinement at 9 A.M. On reaching the house I found her attending to her duties, and, in reply to my questions, she told me that her pains were very trifling, and only occurred at long intervals. Accordingly I left her, being engaged with a more urgent case. Two hours subsequently I was summoned in haste, and informed that the child was born, and that the mother was flooding profusely. On my arrival I found I had been correctly informed; the patient was lying on the bed completely surrounded with blood. I introduced my hand into the uterus, and cleared it of its contents, which consisted of several large clots and a small piece of placenta, which was adherent to the fundus. The hæmorrhage still continuing, and the uterus refusing to contract, I sent for the perchloride, but could only obtain the tincture of perchloride of iron of the Pharmacopœia (the strength of which is one part of strong solution of perchloride of iron to three parts of spirit). I mixed six ounces of this with an equal quantity of water, and injected the whole of the mixture. In about three or four minutes the hæmorrhage returned as freely as ever, the uterus contracting only momentarily. I now injected about six ounces of the tincture of iron alone, and watched the result. The uterus contracted, but only to relax again. By this time a small quantity of the strong solution of perchloride of iron had been procured, and I mixed about three ounces of this with the same quantity of water, and injected it as before; but once more the hæmorrhage returned, and the patient sank.

Not one of the least interesting features of the case is the fact of the patient surviving so long the immense loss of blood, aided, no doubt, by the administration of brandy and milk at frequent intervals. I have used the perchloride on several occasions; but only in rare instances have I had to inject it more than once, and never before have I seen it fail to arrest hæmorrhage.

In conclusion, I may add that the result of the case in question was not due to neglect of any of the precautions necessary to the success of the operation.

I am, Sir, yours obediently,

July 10th, 1875. T. P. Morgan.

How Sanitary Questions are decided in Cambridgeshire.

The following extract is taken from a local paper. We will merely premise that the medical officer of health of the district found occasion to point out the defective condition of the water-supply:—

> "Effects of Impure Water.—In consequence of recent unfavourable reports respecting the Chatteris water, we have been supplied with the following facts:—Five widows and two widowers are living down the New-road, who met together last week at a tea party, all being members of the Zion Chapel, whose united ages amount to 496 years; eight old people living in Slade-end, whose average age is 80 years, and one old lady, who had her portrait taken the other day, prides herself on having lived 92 years. In the face of Mr. Apjohn's report, they all believe in the purity of Chatteris water."

Surely no more conclusive testimony could be given of the wholesomeness of the water. The results of analysis are as nought beside such evidence.

Mr. John Russell, (Neath.)—Such cases will occasionally occur, and unfortunately there is no appeal. We do not think any good would result from the publication of our correspondent's letter.

Medical Officers of Health and Parish Medical Officers.

Dr. Woodward, of Worcester, has written a letter to the Board of Guardians, explaining his unwillingness to supply returns of infectious cases to the medical officer of health unless specially remunerated for doing so.

A Dualist, (Manchester.)—A capital article on Syphilis by Bäumler appears in the third volume of Ziemssen's Encyclopædia of Medicine, just published.

The Profession in the United States.

To the Editor of The Lancet.

Sir,—Allow us respectfully to refer your readers to the "Medical Register and Directory" of the United States," recently published by us. In it will be found full information on the point raised by a correspondent in your last. The systems and institutions for qualification and the number of medical men in each State are fully given, as well as much valuable information not obtainable of any other published source.

Your obedient servants,

Baillière, Tindall, and Cox.

King William-street, Strand, July, 1875.

Anatomical Peculiarity of the Japanese.

Dr. Hilgendorf, of the German Society at Yeddo for the study of natural history, is credited with the observation that the malar bone of the Japanese is double in many cases. The additional bone, when present, is united to the other by a suture, and is believed by Dr. Hilgendorf to be peculiar to the natives of Japan.

The New Fever Department of the Sussex County Hospital.

To the Editor of The Lancet.

Sir,—In reply to Dr. Kebbell's letter in the last number of your journal, I beg leave to agree with him that there has been a great deal of misrepresentation, although not on my part, on the subject on which he has written as, for instance, an assertion that the article which appeared in The Lance some weeks since was inspired by your humble servant, which, as you can testify, was totally unfounded. Dr. Kebbell has written many letters to the local press on the subject in dispute; while up to the present time I have not written to any journal, local or otherwise, and should not do so now had not Dr. Kebbell indirectly accused me of misrepresentation.

In the very laconic letter which I received from the secretary to the hospital, the new fever department, as Dr. Kebbell now chooses to call it, was designated "a building for the reception of fever and other infectious diseases." In a subsequent letter to the Town Clerk it was called "a sanatorium for erysipelas and other allied diseases, so injurious to patients after accidents and operations." Here we have a complete change of front, and, as I consider, a scarcely honest one, and a false issue is raised. Is it not a preposterous euphemism to call a county fever hospital an erisipelas adjunct? An endeavour is made to make the removal of erysipelas cases the primary reason for erecting the new fever hospital and that of the allied diseases (scarlet fever, diphtheria, typhoid fever, &c.) a mere secondary one. All this at first sight seems plausible; but has it not struck Dr. Kebbell that even after the erysipelas and allied diseases have been removed to the new fever department, the patients after operations and accidents will still be liable to erysipelas if kept in the main building, where they will still be exposed to all those conditions which may be the cause of that disease, such as the emanations given off wherever a number of sick persons are collected or congregated, faulty ventilation, and other insanitary arrangements. If Dr. Kebbell wants a remedy for this state of things, let him remove the patients after operations and accidents into the new building, and so remove them out of the atmosphere of the general hospital. I have never for a moment disputed the desirability of removing the fever and erysipelatous cases out of the main building; but what I suggested was, that as they were to be so removed, why not carry the improvement to its fullest extent, and take them to a safe distance from the population. The matter does not admit of any argument; for if it is right to remove them so short a distance, it must be still better to take them further.

There is no analogy between the cases of London and Brighton. The former is a vast city of nearly four million inhabitants, where there manifestly must be some difficulty in getting a proper site for a fever hospital sufficiently isolated, and yet at a convenient distance from the parts from whence the patients are drawn. Dr. Sibson, in his evidence before the Select Committee of the House of Commons, lays down that distance as three miles. The Sussex County Hospital is nearly three miles from the western extremity of Brighton, and I am sure an eligible site for a fever hospital could be obtained in a situation nearer the central and western parts of the town than the County Hospital. Dr. Kebbell has himself indicated one spot much more isolated—namely, the Parish Infirmary, which the guardians have always kindly allowed to be used in cases of epidemics. What is the practice at present at the County Hospital? It is this. Whenever a case of small-pox is sent there, it is forwarded on at once to the Parish Infirmary. Does not this point to some extent to a solution of the difficulty? If a joint action of the hospital authorities, the guardians, and the sanitary authority were to take place, the difficulty, if any existed, would soon be removed. Dr. Kebbell would only prepare for epidemics. I would do this, but also would, in addition, try to prevent their occurrence. Dr. Kebbell is medical officer of health for Hove, and advocates the transplanting of fever cases from that part to Kemp Town, the extremity of the borough of Brighton, for which I am medical officer of health. I advocate an isolated hospital, which shall be beneficial equally to all parts; that would provide not only for epidemics, but also for the ordinary wants of the town, in order to prevent epidemics, and into which the sending fever patients from the country districts (Dr. Kebbell's hospital being a *county* one) would not be likely to become the means of importing infectious diseases into Brighton. It seems to me astounding that Dr. Kebbell or anyone else can advocate the collection and treatment of cases of infectious disease, no matter how few in number, in a situation close to two asylums for children, the one having at the present time 29 inmates, the other 70, and in last March 116. There is another institution (St. Mary's Hall) not very far off, with 100 pupils, 20 teachers, and 20 servants; total 140. There is also the Brighton College, the Deaf and Dumb Asylum, and a large number of first-class schools in Kemp Town. Dr. Kebbell cannot see any objections to his contemplated fever hospital. I think I have shown him many. Dr. Letheby, in his evidence before the Select Committee (now sitting) of the House of Commons, said: "As a professional man, from the attention he had given to the matter, he believed that it was of the first importance that a hospital for contagious and infectious diseases should not be in a residential district, or in a place where many persons were continually passing by it, for there was no doubt that infection would be spread in this way. He also gave it as his opinion that such hospitals should stand on elevated ground, instead of in a hollow, and away from public thoroughfares." I am of opinion that it is not only wrong to perpetuate a dangerous practice, which has hitherto prevailed, of sending cases of contagious disease for treatment into a thickly populated town like Brighton, but that it inflicts an additional wrong by increasing the zymotic death-rate of the borough, whilst it in the same proportion lessens that of other districts.

I am fully persuaded that so benevolent a lady as Miss Poore has shown herself to be would not have made the least difficulty if the case had been properly represented to her. For what would it matter to her whether the proposed fever hospital or department was close to the main building or a mile or two away from it? The specific object for which she gave the donation would still have been carried out.

I remain, Sir, yours &c.,

R. P. B. Taaffe, M.D. Lond.,

July 19th, 1875. Medical Officer of Health for Brighton.

Diarrhœa in Children.

Dr. Langmore is thanked for the copy of the "Plain Rules for the Prevention and Treatment of Diarrhœa in Children" distributed among the poor of the dispensary and neighbourhood. They seem to us very good for the purpose, and it would be well if such papers could be extensively distributed. Infantile diarrhœa is a disease so common, and yet so grave, and withal dependent to so large an extent on causes of a preventable character in regard to which the people are ignorant, that such tracts as that under notice are likely to be very useful.

Mr. E. George, (Horncastle.)—The preliminary examination at either the College of Surgeons or Apothecaries' Hall.

Scilla.—Ten days is not a long time. It is not wise to formulate iron rules of conduct in all the different circumstances specified in the three cases put to us. In all events it is better to act magnanimously, and upon a generous construction of the conduct of professional neighbours.

Mr. C. J. Ottley.—We never recommend a particular physician or surgeon.

Case of Displacement of the Seventh Cervical from the First Dorsal Vertebra, without Fracture.

To the Editor of The Lancet.

Sir,—J. C——, aged forty-two, a strong muscular man, on May 22nd, whilst under the influence of drink, was engaged in a wrestling encounter. When down on his hands and knees, his opponent placed one hand between his thighs, the other at the back of his neck, and turned him over, so that his head was doubled under his chest. He held him in that position about half a minute, and after releasing him it was found he could not stand. Two hours afterwards I saw him, and diagnosed displacement of the seventh cervical from the first dorsal vertebra, causing pressure on, and tension of, the cord. He was quite conscious, and remained so until a few hours before his death. There was considerable tenderness over the seat of injury, complete loss of motor power and sensibility in the lower extremities, and of sensibility in the trunk below the seat of injury; motion and sensibility somewhat impaired in the upper extremities; priapism and spermatorrhœa. I drew off his urine, applied leeches and hot fomentations, prescribed bromide of potassium, and administered a turpentine enema. He got gradually worse until the third day, when total loss of motion and sensibility in the upper extremities came on, and he died comatose.

In my absence, Mr. Couldrey made a necropsy twenty-nine hours after death. There was considerable ecchymosis over the seat of injury; marked separation between the spinous processes of the seventh cervical and first dorsal vertebra on exposing the spine; the supra- and inter-spinous ligaments ruptured; the ligamenta subflava stretched and partially torn; the dura mater congested, and the spinal cord softened from seat of injury to the brain; the posterior common ligament torn through, the anterior one unruptured. There was no fracture. Brain congested; cerebellum very much softened. An examination of the thorax and abdomen was not deemed necessary.

Yours &c.,
Littleborough, July, 1875. G. K. Pitcairn.

Lectures on Insanity.

Dr. Yellowlees, Physician-Superintendent of the Royal Asylum at Gartnavel, has during the last three months given a course of lectures on Mental Diseases at the University of Glasgow, accompanied by clinical demonstrations at the asylum. At the conclusion of the lectures on the 17th inst., an address was presented to Dr. Yellowlees in acknowledgment of his services.

Medical Appointments in the Dutch Navy.

Gat, Surgeon (Dewsbury), would be glad to be informed where he could get the Dutch Navy Medical Regulations.

Statist.—Yes, in Dr. Lagneau's paper recently read before the Parisian Academy of Moral and Political Sciences on the "Influence of Illegitimacy on Mortality." Out of every 1000 children born of unmarried parents, only 238 reach 21 years of age; whereas of children born in wedlock, 640 out of every 1000 attain their majority.

Zero.—We have no information on the subject. It could not be registered in England.

Coroners' Inquests.

At this juncture the following paragraph, taken from the *Local Government Chronicle*, may prove interesting:—

> "The Middlesex justices, at their next meeting, will have laid before them the opinion of counsel on questions submitted to them respecting the holding of unnecessary inquests by coroners. The opinion of Mr. Manisty and Mr. F. W. E. Everitt is as follows:—'If an inquest has been in fact held, and the expenses have been really and *bonâ fide* paid, the justices have no right to disallow the payment of such expenses. If it could be shown that they had not been incurred and paid *bonâ fide*, we think the justices might properly refuse to pay them, leaving the coroner to apply for a mandamus; in which case, if any *mala fides* on his part were proved, the Court would probably refuse to assist him. If, at the expiration of the current five years, the justices should be of opinion that unnecessary inquests have been held, it will be competent to them to take that circumstance into consideration in fixing the amount of the coroner's salary for the next five years. If, in the opinion of the justices, the coroner misconducts himself by holding inquests unnecessarily and vexatiously, the only course open to them during the current five years seems to be to bring the matter under the consideration of the Lord Chancellor.'"

W. C. M., (St. Andrews.)—The "Handbuch der gesammten Augenheilkunde," by Proff. Arlt, Arnold, and others. This important work, in which Proff. Alfred Graefe and Saemisch have a considerable share, is exceptionally good on that little cultivated branch of ophthalmic science, the "Organology of the Eye." Chapter VIII., on the Circulation and Nutrition of the Eye, is particularly well done. It is from the pen of Prof. Leber.

Mr. H. W. Kiallmark.—We will endeavour to do so.

Turkish Baths in France.

M. Leudet lately read a paper before the Hydrological Society of Paris, in which he described the Turkish baths of Hamburg and Scandinavia. In 1872 the same author had offered a sketch of similar establishments in England, Ireland, and Scotland. He laments greatly that France should be so sadly behindhand in this respect. No doubt the French are more accustomed to public baths than we are in this country, as complete domestic ablutions are with us more common than with them; but it is to be regretted that the French should ignore the great advantages which, in appropriate cases, attend the use of Turkish baths.

The Indian Medical Service.

To the Editor of The Lancet.

Sir,—Knowing that you are at all times ready to open the columns of your valuable journal for the purpose of bringing before the medical profession and those about to enter it any injustice and hardships inflicted upon men who have been induced by the promise of high pay and emoluments to enter a public service, allow me to trespass upon your kindness in order to inform those who are about entering the Indian medical service to think seriously before doing so. I will, then, briefly notice a few facts which intending candidates for the service may have to encounter should they embark upon an Indian career.

1st. With reference to pay. On arrival in India, a surgeon draws 286 r. 10 a. per mensem, about £300 per annum. This is just sufficient to enable him to exist, for since the great increase in the price of necessaries within the last few years, to save money out of this sum is impossible. To this amount he is restricted until he has passed the examination in the Hindustani language. So say the Regulations. This then is done as soon as possible, in order to qualify for higher pay.

2nd. After passing the examination in the language comes the first blow to his hopes of higher pay and improved position. Instead of being located permanently with a regiment, he is ordered about, first in one direction, then in another, remaining two months in one place, three in another, and so on, these journeys often extending over three and four hundred miles, and the expenses of which frequently have to be borne by the unfortunate officer. This continuous change of station may continue for two or three years, according to the amount of interest he may have at head-quarters. The fortunate may by this time obtain an appointment; the unfortunate, or those who have no interest, may continue to be sent about the country until, wearying of such a life, they obtain a sick certificate to England, disgusted with everything connected with the service, having lost three or four of the best years of their lives, which might have been spent more profitably at home.

3rd. For five or six years a medical officer often is, although entitled after five years' service to 600 r. per mensem, restricted to 300 r. per mensem, with an additional 100 r. with a regiment, because he is only acting—but performing exactly the same amount of work—for an officer who may be in England or elsewhere. When this state of things continues over a period of two or more years, it becomes hard and unjust.

4th. With reference to the future. After twenty-five years of Indian service, an officer may retire upon £365 per annum. Often he may be worn out from long service, and unfit for any further exertion as far as earning money is concerned. I ask you, Sir, do you consider £365 per annum, looking to the present rate of prices in England, a sufficient reward for an officer who has toiled for a period of twenty-five years in an unhealthy climate? Prior to 1864, officers who entered the service had the advantage of subscribing to a Fund, under the regulations of which, on retirement, they were granted an annuity of £200 or £400 in addition to the pension. No such Fund exists now. The reason why is only known to the authorities at the India Office. He has nothing, therefore, to look to but an inadequate pension as a means of subsistence in his old age.

I remain, Sir, your obedient servant,
Madras, June 2nd, 1875. Surgeon of Five Years' Standing.

To the Editor of The Lancet.

Sir,—In my Lancet received by the last mail I see a letter on the Indian medical service, signed by "Medicus," in which he certainly states the feelings of all the younger members of that service whom I have come across. The memorandum which he quotes states in paragraphs 8 and 9 the various rates of pay to be drawn by medical officers of the different ranks, both unemployed and in charge of regiments; but in no single place is there the slightest mention of *officiating allowances*, the way of calculating which not only bothers the new-comer, but also many high up in the list. I enclose a table showing the way in which this is done, and feel sure you will fully agree with us in considering it a great anomaly, not to say a decided grievance, that for doing exactly the same duty one officer should draw 148 r. 0 a. 11 p. in addition to his unemployed pay, while another receives but 55 r. 10 a. To explain this more fully, let us take two surgeons of eighteen months' standing (this is about the time when they may expect to commence *officiating*). A. is sent to one regiment, the permanent incumbent of which is a surgeon-major of twenty-five years' service. His monthly salary will be, unemployed pay of rank, 286 r. 10 a., plus 55 r. 10 a., which is half the difference between the consolidated and unemployed pay of the permanent incumbent, the two sums amounting to 342 r. 4 a. B., who is perhaps lower down in the list, is, however, more fortunate, and is sent to officiate for a surgeon of over five years' service. He will get 286 r. 10 a. and 148 r. 0 a. 11 p., or a total of 434 r. 10 a. 11 p. It is true these are the extremes; but the above has often occurred, and is likely to do so over and over again. Why should not the medical allowances for a regiment be a fixed sum, as in the case of adjutants, quartermasters, and, in fact, every other officer in a regiment? A certain amount of work and responsibility is attached to the appointment, and a certain sum ought to be paid in return for it. The reason the India Office does not make it clear to intending applicants for appointments what they are really to expect is, of course, unknown to most of us; but the sooner the matter is put upon a better footing the less discontent there will be, and all know that to commence one's career with this destroys zeal to a very great extent.

Your obedient servant,
June 8th, 1875. Surgeon, Indian Medical Department.

P.S.—I may state there are not many of us who have not been retrenched at one time or another (in one case to the amount of about 2000 r.) through not being aware of the rules relating to officiating allowances. This is the painful way we first became acquainted with them.

A Third Dentition at Ninety Years of Age.

A case of this kind is published in the *Allg. Med. Central Zeit.*, June 21st, 1875. The subject of it was a woman in the Hospital for Incurables at Paris, who found, in her ninetieth year, all her teeth grow again. At the age of forty-seven and again at sixty-three, she had had a new set. The head surgeon of the hospital, who has occupied his post these fifty years, had occasion to witness this extraordinary dentition. In bringing this case before the Academy of Sciences, he referred to Hunter, Jobert de Lamballe, and Petrequin, who had observed similar cases, but not at so late an age.

Mr. G. Skene (Castle Douglas) sends us an account of a method for preventing a "host of diseases depending on deranged alimentary canal," and so doing away with "the practice of physicing children." "An enema given once a day will thoroly prevent any viscious secretion from loding and causing after trouble." The extracts, which we have given *literatim*, are at the service of our readers.

Dr. Woodhouse.—We sympathise acutely with Dr. Woodhouse. We cannot doubt that the letter of Mr. Tasker Evans, jun., was written under a misapprehension of the facts of the case.

F. W., (St. Albans.)—Medical men do not generally dispense in that city. We cannot speak as to the probability of one being able to follow the two occupations mentioned.

Mr. W. Adams.—Another instance, which we happen to remember, is that of Dr. Ede, of Barnsbury, London, who, doubtless, would give particulars to our correspondent.

Communications not noticed in the current number will receive attention in our issue of the ensuing week.

Communications, Letters, &c., have been received from—Mr. Henry Lee, London; Dr. G. Johnson, London; Dr. Hughlings Jackson, London; Mr. James Lane, London; Mr. M. Tupper, London; Dr. Quinton, Deal; Messrs. Baillière, Tindal, and Cox, London; Dr. More Madden, Dublin; Dr. Payne, London; Mr. Ayling, London; Mr. Orchard; Dr. Gillespie, London; Mr. Hemming, Bristol; Surgeon-Major Hunter; Mr. S. Snell, Sheffield; Mr. M'Gann, Mysore; Mr. Alcock; Dr. M. Brown, Edinburgh; Dr. F. Alsop, Edinburgh; Mr. Macdonald, Manchester; Dr. Lomas, London; Mr. Blackett, London; Mr. Shackles, Hull; Mr. Newstead, London; Mr. Willing, Great Wakering; Mr. Palmer, Mortlake; Dr. Taaffe, Brighton; Mr. Chitty, Shaftesbury; Mr. Plimsoll, London; Mr. Watts, Hartfield; Rev. THE
ADDRESS IN MEDICINE,

Delivered before the Annual Meeting of the British Medical Association, at Edinburgh, August, 1875.

By J. WARBURTON BEGBIE, M.D., F.R.S.E.

ANCIENT AND MODERN PRACTICE OF MEDICINE.

When the late distinguished Professor of Logic and Metaphysics in the University of Edinburgh inquired, "Has the *practice* of medicine made a single step since Hippocrates?" and, in vindication of his own belief in the negative conclusion, referred to the recorded opinions of several eminent authorities of modern times in the profession, he put a question which no thoughtful mind within the pale of medicine will be inclined to evade, and the consideration of which, after some sort, may suitably engage our attention in such a meeting as the present.

Sir William Hamilton, in penning the question referred to, had under review "An Account of the Life, Lectures, and Writings of William Cullen, M.D., the famous Professor of the Practice of Medicine in the University of Edinburgh from 1769 to 1790," by Dr. John Thomson; and having noticed, in terms of well-deserved commendation, the masterly execution of his task by the eminent author of the "Lectures on Inflammation," and accompanied him in a brief survey of the doctrines promulgated by the renowned triumvirate of the early part of the eighteenth century—to wit, Hoffmann, Stahl, and Boerhaave,—he was tempted by a mild reflection of Cullen on the practice of Stahl, which censure, indeed, was judged too indiscriminating by Dr. Thomson, to indulge in a philippic against the modern practitioners of the healing art, quoting what for his purpose appeared to be the apposite phrase of Hoffmann, "Fuge medicos et medicamenta si vis esse salvus," and that of Celsus, "Optima medicina est non uti medicinâ." The vehemence of Sir William Hamilton's denunciation is more fully explained by a note, published in 1853, to the original article, which had appeared in the *Edinburgh Review* for July, 1832, where it is shown that the dangers which are to be apprehended in the practice of medicine arise, in Sir William Hamilton's opinion, from the illiterate rashness of its practitioners, for he transfers to his pages, with very evident satisfaction, the statement of Dr. Gregory: "I think it more than possible that in fifty or a hundred years the business of physician will not be regarded, even in England, as either a learned or a liberal profession." If the medical faculty of the University of Edinburgh had in any measure justly laid itself open to the charge of hastening the decadence of learning in the profession, it will be admitted by every dispassionate inquirer that the statutes and regulations of that University relative to degrees in medicine entitle it, at the present time, to be regarded as in the van of those bodies which are striving for the honour and advance of the medical profession. It is, indeed, impossible to read the animadversions of Sir William Hamilton without coming to the conclusion that learning in the practitioners of medicine, by which he evidently understood general culture and, in particular, classical attainments, was, in his opinion, the great desideratum. Between learning of the nature referred to, and usefulness in medicine, as dependent upon ample professional qualifications, there is really nothing antagonistic. Not a few of the most distinguished men in the profession in quite recent times have been accomplished scholars. But, while this holds true, let it be distinctly understood that learning of the kind in question is not supreme: it is secondary in importance to ability in the healing art. I make bold to say that not a few physicians, with no pretension whatever to learning, have served their generation well, and have done much to recommend the profession they zealously cultivated, if they cannot be said to have adorned it. If, therefore, it were necessary to decide between the claims of medicine as a learned or so-called liberal profession and as a useful art, the preference must be awarded to the latter. Let us be thankful, however, that no such issue is before us. Medicine *is* a liberal profession, and will doubtless continue to be so, although the diffusion throughout its ranks of polite learning may have become diminished, a result which is to be in no small measure attributed to the very great enlargement which has taken place in all that is proper to medicine itself. Think of the rapid advances which have been made during the last thirty years in such departments of medicine as animal chemistry, physiology, pathology, and psychology, and then consider how limited is the time at the disposal of him who is expected to acquire at least a competent knowledge of these sciences for the cultivation of other subjects, however elevating and attractive. That there exists nothing hostile in the study of medicine, as now pursued, to distinction in other walks, is evident from the circumstance that members of our profession in no way favourably placed for the study have achieved distinction in scholarship. Look at the career of the late Francis Adams, toiling as a country surgeon in Aberdeenshire, and yet distinguished as the translator of Hippocrates, Aretæus, and Paulus Ægineta. Who can fail to sympathise with the feelings of that accomplished man when, in drawing his *magnum opus* to a close, he thus expressed himself: "I shall conclude this argument and my present task by quoting the memorable words in which Cicero apologises for his having spent a certain portion of his time in the cultivation of elegant literature and of philosophy, leaving the reader to apply the same in the case of Hippocrates, and, I may be permitted to add, in that of the humble editor of the present volume, who trusts he shall not be set down as an idle and unprofitable practitioner of the art because he has found leisure, amidst the turmoil and distraction of a professional life, to communicate to his countrymen the important opinions contained in the genuine remains of the Coan sage."

It has been my happy lot to meet with others who, although less distinguished, some indeed wholly unknown to fame, have cultivated, in circumstances quite as trying, their natural taste for classical and other learning; in remote districts of the country, undergoing a daily round of fatigue and anxiety, which must needs try the strength both of body and mind to the very utmost. Mine, moreover, has been the privilege to meet and have friendly intercourse with men who were ably discharging the duties of their calling, and were at the same time being leant upon by the whole community in which their lot was cast, not only as the advisers in sickness, but as persons on whose counsel and judgment all reliance was to be placed.

> "Along the cool sequester'd vale of life,
> They kept the noiseless tenor of their way."

Having formed the acquaintance of such men, I have with pride reflected on the circumstance that the individuals who were the recipients of so much confidence, and whose friendship was so highly prized, were members of the profession to which we have the happiness to belong. It is not the least of the advantages possessed by membership of this great Association, that in our annual meeting the bands of fellowship among us are apt to be greatly strengthened.

The question of Sir William Hamilton, to which reference has been made, leads us, in the first place, to a brief consideration of the practice of medicine at the period of Hippocrates.

Intimately acquainted as Sir William Hamilton was with the whole history of philosophy, he knew the close alliance which existed between philosophy and medicine in ancient times. The most renowned philosophers antecedent to, and contemporaneous with, Hippocrates, applied themselves to the study of medicine. Numerous are the references to medicine in the writings of these philosophers. Take, for example, the following passage from the "Phædrus" of Plato, in which not only is the relation referred to, but the name of Hippocrates is introduced.

"Socrates remarks: Rhetoric is like medicine.—Phædrus: How is that?—Socrates: Why, because medicine has to define the nature of the body, and rhetoric of the soul, if you would proceed not empirically but scientifically; in the one case, to impart health and strength by giving medicine and food; in the other, to implant the conviction which you require by the right use of words and principles.—Phædrus: You are probably right in that.—Socrates: And do you think that you can know the nature of the soul intelligently without knowing the nature of the whole?—Phædrus: Hippocrates, the Asclepiad, says that this is the only method of procedure by which the nature of the body can be understood.—Socrates: Yes, friend, and he says truly. Still, we ought not to be content with the name of Hippocrates, but to examine and see whether he has reason on his side.—Phædrus: True.—Socrates: Then consider what this is which Hippocrates says, and which right reason says about this or any other nature."*

But, while occupied with the study of medicine and engaged in speculations as to the phenomena of disease, it is in the highest degree improbable that these philosophers ever practisėd the healing art. It is, indeed, worthy of remark that in subsequent, although still ancient, times, the intimate connexion which had subsisted between philosophy and medicine was not regarded as favourable to the growth of the latter, and the share he had in effecting their divorcement is held by Celsus as a reason for eulogising Hippocrates. "Hujus autem, ut quidam crediderunt, discipulus Hippocrates Cous, primus quidem ex omnibus memoriâ dignis, ab studio sapientiæ disciplinam hanc separavit, vir et arte et facundiâ insignis" (*De Medicinâ*, liber primus). Medicine, however, had been cultivated after a fashion long antecedent to the birthtime of philosophy. The doctor-priests of the Grecian temples, or Asclepiadæ, had acknowledged Æsculapius as its origin. The Asclepia, or temples, were erected in many parts of Greece, were ruled by the Asclepiadæ, and used in a manner not very unlike that in which hospitals are employed in modern times. To them the sick resorted for advice and cure. In one of the most distinguished of these temples—namely, that of Cos, built on the island of the same name, one of the Sporades, a group of scattered islands, as their appellation denotes, in the Ægean Sea, off the island of Crete and west coast of Asia Minor, Hippocrates, inheriting a recognised position, acted as an Æsculapian priest. He had been born, in all probability, in the four hundred and sixtieth year before the birth of Christ. But Hippocrates had not only the advantage of the most favourable study in the Asclepion of Cos; we know, on excellent authority, that, under the direction of Herodicus of Selymbria in Thrace, he became intimately acquainted with the practice then pursued in the gymnasia, while, through the instructions of Gorgias and Democritus, the former of Leontini in Sicily, the latter of Abdera in Thrace, and himself illustrious as the originator of the doctrine of atoms, he became thoroughly versed in the literature and philosophy of the age.

The foundation of the practice of Hippocrates, with which we are now more immediately concerned, was experience; but this experience of Hippocrates was rational in character, not a mere blind or misguided empiricism. No one could be more convinced of the fallaciousness of a blind empiricism than he was, and his condemnation of it may be recognised in the earliest, the best known, and perhaps the grandest of all the Hippocratic aphorisms, "*ἡ πεῖρα σφαλερή, ἡ κρίσις χαλεπή*," "experimentum periculosum, judicium difficile." Hippocrates believed in the existence of a principle, a spiritual essence, the preserver of all things in nature, the restorer of whatever had become disordered. The regulation and superintendence of all the actions of the system were due to this principle, to which he gave the name of *Φύσις*, Nature. Thus, he was led to consider that the chief duty of the physician consisted in watching the operations of Nature, endeavouring, as might be the case, to promote or restrain these, possibly in some, but these very rare instances, to counteract them. "Our natures," he remarks, or, if not he, one of his immediate descendants, who may reasonably be supposed to be expressing the views of his master, "our natures are the physicians of our diseases." *Νοῦσων φύσεις ἰητρόι.* It is in reference to this exposition of the function at once of nature and the physician in relation to disease that Sydenham, "the chief of English practical physicians," who in many particulars resembled the Father of Medicine, observes: "He it is whom we can never duly praise. He it is who then laid the solid and immovable foundation for the whole superstructure of medicine when he taught that 'our natures are the physicians of our diseases.'" And, again, "The great sagacity of this man had discovered that nature by herself determines diseases and is of herself sufficient in all things against all of them." The belief which Hippocrates had in this "vis conservatrix," "vis naturæ medicatrix," would, in the first place, make him, as we know from his writings he really was, a very close observer of the operations of nature. It would further render him cautious in regard to interference with these, and resolute in his determination "to have two special objects in view with regard to diseases—namely, to do good, and to do no harm." There is, however, no ground for concluding that Hippocrates was an inert or purely expectant practitioner. On the contrary, there is abundant proof in the works which bear his name that, in limiting, as Sydenham has expressed it, "the province of medical art to the support of Nature when she was enfeebled, and to the coercion of her when she was outrageous," Hippocrates found occasion to be bold and decided in his method of treatment. His employment of powerful remedies is best exhibited in the instances of diseases which, according to the humoral doctrine promulgated by him, were to be relieved by the discharge of some peccant humour. Evacuants of various kinds were used with this intention, purgatives more especially, but likewise emetics, diuretics, and sudorifics. He drew blood by means of the lancet, the scarificator, and the cupping instrument, but with what careful consideration and thoughtfulness is well shown in the treatise *Περὶ Διαιτης Ὀξέων* ("On the Regimen in Acute Diseases"), in which he remarks concerning the treatment of pleuritis: "But if the pain be not removed by the fomentations, we ought not to foment for a long time, for this dries the lungs, and promotes suppuration; but if the pain point to the clavicle, or if there be heaviness in the arm, or about the breast, or above the diaphragm, one should open the inner vein at the elbow, and not hesitate to abstract a large quantity of blood, until it becomes much redder, or, instead of being pure red, it becomes livid; for both these states occur." What forcibly strikes the reader of the passage now quoted, and of those passages which immediately precede and follow it, is, as indeed Galen among the ancient, and many of the modern, commentators of Hippocrates have carefully noted, the manner in which the Father of Medicine commences with the milder means of affording relief from the pain of pleuritis, such as the employment of fomentations, the rules for the preparation and application of which, as laid down by him, are simply admirable; and only in the event of these failing to accomplish the object in view, he counsels that recourse should be had to bloodletting and the use of other powerful remedies, including cathartics. In another part of the same treatise, the following rule is laid down for the employment of bloodletting: "Bleed in the acute affections, if the disease appear strong, and the patients be in the vigour of life, and if they have strength." Surely this is a most cautious limitation of the circumstances in which the remedy is to be, in the mind of the writer, advantageously employed. In one passage, however, if not in more than one of the Hippocratic writings, there is reference made to the production of "deliquium animi," "leipothymia," or "leipopsychia," as the Greeks termed it, by bloodletting in the treatment of acute diseases. This rule, which was opposed by the ancient authorities generally, cannot be said to have been invariably acted upon by Hippocrates.

A study of the method of treatment pursued by the Father of Medicine and his immediate descendants exhibits the fact that their rules of procedure were all based on experience. He had the merit of discovering the great truth that accurate observation in medicine is the real foundation of all knowledge, and he proceeded in the true spirit of the inductive philosophy to generalise solely from the phenomena thus observed. It can never cease to afford material for wonder that through the genius of one man so much was accomplished, when we reflect on the circumstance that in the time of Hippocrates human anatomy had scarcely, if at all, been practised, that physiology was virtually unknown, and the use of remedial agents was almost entirely limited to articles of the vegetable kingdom, and these the indigenous plants of Greece and the neighbouring countries. To the subject of diet and regimen, however, Hippocrates paid the greatest attention. In the Hippocratic writings there occur terms which exactly correspond with those we so frequently employ; full, ordinary, and low diet. In the treatise *Περὶ Ἀγμῶν*, the following passage occurs:—"A diet slightly restricted will be sufficient in those cases in which there was no external wound at first, or when the bone does not protrude; but one should live rather sparingly until the tenth day, as being now deprived of exercise; and tender articles of food should be used, such as moderately loosen the bowels; but one should abstain altogether from flesh and wine, and then by degrees resume a more nourishing diet." And so, not to multiply quotations, in the treatise already referred to, and in Ἀφορισμοί, there are many interesting and instructive suggestions to be found regarding the administration of food and wine. It is sufficient, in passing, to make a brief reference to the paramount importance Hippocrates attached to the doctrine of crisis, and to the bearing which this had on the treatment of diseases. The doctrine of crisis, indeed, was an essential part of his system of humoralism, and had in consequence an intimate connexion with the method of treatment he pursued. Critical events were evacuations of different kinds, occurring chiefly by the skin, bowels, and kidneys.

---

* The Dialogues of Plato. By B. Jowett, M.A., vol. i., p. 605.

With the views he entertained as to crisis, there is further intimately blended the so-called Hippocratic doctrine of critical days. Galen expressly affirms that Hippocrates was the first author who treated of these, but whether this be true or not, we know that he attached very considerable importance to the doctrine. "Fevers," he remarks, "come to a crisis on the same days as to number on which men recover and die." It was the particular attention given by Hippocrates to the tendencies manifested by diseases to recovery, or, on the other hand, to an unfavourable termination, also to the occurrence of evacuations or of crises in their course, that led to the remarkable care with which he studied the whole subject of prognosis. There is no more interesting or valuable work in the whole Hippocratic collection than the one entitled Προγνωστικόν, Prænotiones, Prognostics; and happily, concerning its authenticity, as the undoubtedly genuine work of the Father of Medicine himself, there has never been any question.

Again, we should be doing serious injustice to the Father of Medicine were we not to notice, and that in terms of the very highest commendation, the profound sagacity exhibited by him in the observation of the influence of external agents on men in health and on disease. This is fully exhibited in the treatise Περὶ Ἀερῶν, Ὑδατῶν, Τοπῶν, in which the operation of the atmosphere, of particular seasons, situation, and dwellings of the people, in the production of health and diseases of different kinds is discussed. Dr. Adams says of it that "it relates to a subject of commanding interest, and deserves to be carefully studied, as containing the oldest exposition which we possess of the opinions entertained by an original and enlightened mind on many important questions connected with public hygiene and political economy, two sciences which of late years have commanded a large amount of professional attention." Since this passage was written by Dr. Adams, greatly increased interest has been awakened in these subjects. I venture to affirm that the most enlightened inquirer concerning public health, be he legislator or physician, will find much to instruct him in the pages of Hippocrates.

The narration of individual cases of disease commenced with Hippocrates; he may, indeed, be said to have been the originator of the clinical study of medicine. By way of comparison between ancient and modern medicine, some clinical observations of Hippocrates may be quoted in the first place, and thereafter certain passages cited from a modern clinical lecture not unworthy of being placed alongside of the former. In the first book of the *Epidemics*, Ἐπιδημιῶν, α, it is thus written: "Philiscus, who dwelt near the wall, was laid up. On the first day, fever acute; he perspired; night very disturbed. Second day, aggravation of symptoms; in the evening, an injection procured a good stool; night quiet. On the morning of the third day, and up to noon, appeared free from pain; but in the evening, acute fever, with perspiration; thirst, tongue dry; passed black urine; night disturbed; he did not sleep at all; his mind wandered on all subjects. On the fourth day, general paroxysms; urine black; night more endurable; urine of improved colour. On the fifth day, about noon, a little blood escaped from the nostrils; urine varied in appearance with thready clouds resembling semen irregularly suspended in it. The urine did not deposit. A suppository caused passage of some feculent matter with wind. Night distressing; little sleep; talkativeness; delirium; extremities very cold, and could not be warmed; the patient voided black urine; he rested a little towards daybreak; lost speech; had a cold sweat; extremities livid. About the middle of the sixth day he died. The respiration was throughout large and rare, like that of a person who required to be reminded to breathe. The spleen was swollen, and formed a roundish tumour. The perspiration continued to be cold till the end; the paroxysms were on even days." It is to the description here given of the patient's breathing that I wish particularly to call attention. The words employed by Hippocrates are "*Τούτῳ πνεῦμα διὰ τέλεος ἀραιὸν μέγα.*" Galen's commentary on the passage justifies the rendering which has been adopted. Further, we know that the word *ἀραιός*, when used by Hippocrates, whether in reference to the respiration or the pulse, invariably signifies "infrequent," "few in number," "with intervals." Before offering a few observations on this clinical history, I shall give an extract, or rather extracts, from a case recently recorded by Dr. Laycock (*Dublin Journal of Medical Science*, 1873). "J. O'H——, aged fifty-six, labourer, admitted to hospital November 18th, 1863. No family history obtainable. Previously to admission, was employed in sinking a well, which kept him constantly wet; he has not been a temperate man, but enjoyed good health up to four days before his admission. On that day he complained of pain in the chest and some shortness of breath. He attributed this to overwork, but it was so severe as to oblige him to leave off work, and he consequently went to bed. Next day felt better, but the day after he felt very giddy, and was forced to return to bed. On the 17th, about 7 A.M., his wife found him lying half out of bed, and passing urine on the floor; when spoken to, said his left arm felt very heavy, and he could not move it, and that the left leg was the same; he also complained of headache, frontal and temporal, but not severe." Then follows a detailed and interesting statement regarding the patient's condition on admission to the Royal Infirmary. I quote the account of his breathing: "Breathing appears calm for the most part, with frequent intervals of accelerated and laborious breathing. When the act of respiration is suspended, the fact of coughing once or twice does not seem to bring it back; but, if the patient is roused and made to speak, respiration is resumed. The cessation appears to be quite regular in point of time, occupying generally about thirty seconds, and respiration then continues for about twenty-five respirations. The heart's action at such times was accelerated and tumultuous." The progress of the case is recorded as follows. "On December 1st complained of pain in the right side; friction sounds detected; coughs slightly; no expectoration; delirium occurred during the succeeding night; the following morning said he was better, and the ascending and descending respiration was not observed; friction heard in the right infra-axillary region; the right side moved but slightly in respiration, which was chiefly diaphragmatic; dulness was perceived over the right base posteriorly, where also friction and fine crepitation were heard. On the 3rd December the respiratory phenomena were less marked; but on the 4th weeping was observed in the afternoon, although the patient was cheerful about himself, and the peculiar breathing was again manifested. On the 5th heart's action was calmer; œdema of the left hand commenced. On the 9th œdema of the lower part of the left thigh; foot and lower part of leg very cold. On the 12th a fresh pulmonary attack commenced, the left pleura being now the seat. During the three following days there was considerable delirium; he was very troublesome at night, crying out and groaning. On the evening of the 16th he had more frequent paroxysms of apnœa; the cardiac action was hurried, about 130 per minute, but regular. On the 18th the symptoms were found to have subsided somewhat, but on the evening of that day dyspnœa came on, with greatly increased feebleness; pulse about 60, and irregular; respirations hurried and forcible, from 45 to 50 per minute. The pulmonary symptoms had become greatly aggravated, and the patient died about one o'clock on the morning of the 20th. Post-mortem examination was not permitted."

The case of Philiscus, as recorded by Hippocrates, is one of great interest. The occurrence of accession of fever towards the evening of the third day, freedom from fever having been noted in the morning, with supervention of several unfavourable symptoms—in particular, great thirst, dry condition of the tongue, black urine, delirium, and coldness of the extremities,—led Galen, in his Commentary, to remark that the fatal issue of the disease might have been anticipated. It is, however, in respect to the peculiar character of the breathing that the case of Philiscus acquires its chief interest, and it is in this particular that a resemblance is to be found between the ancient and the modern clinical examples now quoted. The attention of Hippocrates had been arrested by the peculiar character of the breathing which existed throughout the fatal illness of Philiscus. Surely it is matter of interest and for reflection that the respiration described by Hippocrates as ἀραιὸν μέγα, "rare and large," and to which Galen has attached the meaning "like a person who forgot for a time the need of breathing, and then suddenly remembered," or "the respiration throughout, like that of a person recollecting himself, was rare and large," has attracted great attention in quite recent times. The expression used by French writers, "besoin de respirer," corresponds in some measure to the meaning which is sought to be conveyed by the Greek words. In Latin, the rendering is "Spiratio huic perpetuo rara et magna fuit." Daremberg, the learned French editor of Hippocrates, thus translates the passage: "La respiration fût constamment grande, rare comme chez quelqu'un qui ne respire que par souvenir." The relation of this peculiar character of the breathing, with which, under the name of "ascending and descending inspiration" of the eminent Dublin physician, Dr. Stokes, the profession is now familiar, to lesion of the nervous system, was of course unknown to Hippocrates, and for many subsequent ages could not be known to those who were ignorant alike of anatomy and physiology. In recent times it has been described by the late Dr. Cheyne, of Dublin. "For several days," wrote Dr. Cheyne, in 1816, in his account of a patient, aged sixty, who had fatty degeneration of the heart, with irregular and intermittent pulse, and whose death was due to apoplexy, "his breathing was irregular; it would cease for a quarter of a minute, then it would become perceptible, though very low, then by degrees it became heaving and quick, and then it would gradually cease again. This revolution in the state of his breathing occupied about a minute, during which there were about thirty acts of respiration." Subsequently Dr. Stokes connected the peculiar respiration with a weakened state of the heart, "a phenomenon to be looked for in many cases of fatty degeneration." I have never seen it, remarks the same authority, except in examples of that disease. In his description of it, Dr. Stokes observes: "It consists in the occurrence of a series of inspirations, increasing to a maximum, and then declining in force and length, until a state of apparent apnœa is established. In this condition the patient may remain for such a length of time as to make his attendants believe that he is dead, when a low inspiration, followed by one more decided, marks the commencement of a new ascending and then descending series of inspirations. This symptom, as occurring in its highest degree, I have only seen during a few weeks previous to the death of a patient. I do not know any more remarkable or characteristic phenomena than those presented in this condition, whether we view the long-continued cessation of the breathing, yet without any suffering on the part of the patient, or the maximum point of the series of inspirations, when the head is thrown back, the shoulders raised, and every muscle of inspiration thrown into the most violent action; yet all this without any râle or sign of mechanical obstruction." Dr. Stokes refers to the fact of the sighing respiration, which is closely allied to the more formidable ascending and descending respiration, being observed in persons who are labouring under certain forms of gastric and hepatic derangement, and in connexion with undeveloped gout, and likewise to the significant fact of Laennec having described a form of asthma with puerile respiration, while the illustrious French physician attributed the malady to some special modification of nervous influence.*

Dr. Little, of Dublin, in an able paper published in 1868, while allying the peculiar breathing, as Dr. Stokes had done, with organic disease of the heart, does not admit its special connexion with fatty degeneration, but believes it to accompany atheroma of the aorta, valvular lesions, and hypertrophy, as well as dilatation of the left ventricle. Dr. Little has suggested as a theory of its causation, that, in consequence of the existence of one or other of the lesions mentioned, there is an unequal action of the two ventricles. Consequently the left ventricle is unable to propel the aerated blood, and stops now and then. This blood, therefore, remains in the lungs, pulmonary veins, and left auricle, and as it has already been fully oxygenated, it no longer stimulates the respiratory centre through the vagus. Thus the venous blood which is requisite to excite the vagus branches is not supplied, consequently respiration ceases, and the breathing takes on this irregular action. By degrees the contractions of the ventricle partially free the auricle and pulmonary veins, venous blood is again sent to the lungs, which stimulates the filaments of the pneumogastric and causes respiration to begin. Dr. Laycock, in his valuable contribution to the pathology of the ascending and descending respiration, or, as he terms it, "recurrent brief apnœa," from which I have already quoted, while offering objections to the completeness of the explanation according to Dr. Little's ingenious theory, does not hesitate to concur in the opinion that the vagus system is involved.

It is worthy of remark that, in the case of Philiscus detailed by Hippocrates, sleeplessness was a notable feature, and although the febrile condition under which the patient laboured may be the explanation of this symptom, it is at least as reasonable to suppose that the neurosis of the vagus on which the peculiarity of his breathing depended was its cause.

Laennec, the illustrious French physician, the modern discoverer of auscultation, he to whom we are indebted for the introduction of auscultation and for the great light which his discovery shed on the diagnosis and treatment of diseases of the chest, has rendered due credit to Hippocrates. To the Father of Medicine, indeed, and to Aretæus, among the ancients, Laennec confesses that he was alone indebted for any information on the subject which he has so signally made his own. He expressly states that Hippocrates practised immediate auscultation. "Hippocrate avait tenté l'auscultation immédiate"; and in proof of his having made trial of this means of diagnosis, he refers to the well-known passage in the treatise Περὶ Νουσῶν, τὸ Δευτέρον, "De Morbis," Liber Secundus, a work which there is good reason for believing, although not composed by Hippocrates himself, was written either by one or more of his contemporaries or by some of his immediate descendants in the school of Cos, in which it is made clear that Hippocrates fell into error in supposing his ability to distinguish between the presence of water and of pus in the chest by the peculiar sound heard on applying the ear. It is in the same chapter, and in close relation to the same subject, that Laennec makes the remarkable statement—a statement which cannot be read without feelings of admiration for the candour and modesty of that distinguished man—that he had read the passage in Hippocrates many years before the commencement of certain experiments in physics, which suggested to him the idea of mediate auscultation, but he never entertained the idea of repeating the experiment of Hippocrates; it passed entirely into forgetfulness; he simply regarded it as one of the errors into which that great man had fallen. But the passage reverted to his mind when he commenced his researches, and he felt surprised that its consideration had not proved suggestive to some readers. The error made by Hippocrates, Laennec further remarks, might have led him to the discovery of many valuable truths. He concludes a remarkable passage in the following words:—"But Hippocrates stopped with an incorrect observation, and his successors overlooked its import. This, at first sight, may appear surprising; nevertheless, nothing is more common. No man is permitted to embrace all the relations and consequences of the most simple fact; and the secrets of nature are more frequently disclosed by accidental circumstances than they are wrested by scientific efforts" ("De l'Auscultation Médiate," Première Partie, Chapitre iii). Under the designation of Hippocratic succussion, we possess, as is well known, a means of physical exploration of the chest which was practised by the Father of Medicine. In the same treatise as that already referred to, the method of procedure in the use of this means is laid down. It is directed that after the patient has been carefully washed with warm water, he is to be placed in a firm seat, and his hands held by an assistant; the physician, meantime, taking him by the shoulders, shakes him, and attentively listens in order to determine on which side of the chest a sound is occasioned. Further, the rules for the treatment of empyema by operation are given with precision: it is directed that recourse is not to be had to paracentesis before the fifteenth day from the commencement of the effusion; where pain is chiefly felt and swelling is most conspicuous, the opening is to be made, while a preliminary incision through the integuments precedes the penetration of the pleura effected by a sharper and more pointed instrument, protected by a piece of cloth. In some instances, it is mentioned, the perforation of the thoracic parietes was made, not through an intercostal space but through a rib, a plan revived in recent times by M. Reybard. When a sufficient quantity of pus has been permitted to flow, the wound is to be closed by means of a portion of linen cloth attached to a thread. Daily a similar quantity of pus is to be evacuated. On the tenth day, when the whole of the collection has been allowed to escape, a mixture of tepid oil and wine is to be injected through the opening, for the purpose of cleansing the lung. This part of the operation is to be practised twice daily, the injection of the morning being withdrawn and replaced by a fresh quantity in the evening, and so on. At length, when the purulent fluid has become clear and thin, a metallic sound is to be introduced, the size of which is to be gradually lessened as the fluid itself diminishes; thus, the wound is permitted to cicatrise.

---

* Cependant le malade étouffe; et, comme nous venons de le dire, il aurait besoin d'une respiration plus étendue que celle que permit son organisation: ou, en d'autres termes, la expiration est très parfaite, le besoin seul de respirer est augmenté. Ce n'est pas dans le poumon qu'il faut chercher la cause de la maladie; et lors même qu'adoptant en entier la théorie chimique de la respiration, on voudrait supposer qu'un besoin extraordinaire d'oxygenation du sang est la cause de la dyspnée, il faudrait encore remonter plus haut et reconnaître que le mal est dans l'innervation même.

The interest attached to the description now quoted is heightened by a consideration of certain shrewd observations bearing on the same subject, and which occur, not in the same treatise alone, but in other of the Hippocratic works, notably in the book of "Aphorisms." An empyema on the left side, the author remarks, is less dangerous than on the right. When the pus was clear, and studded more or less with sanguinolent threads, that appearance indicated the probability of a satisfactory recovery; but, on the other hand, if, on the first day of its removal, the fluid possessed a colour like the yelk of egg, while on the succeeding day it was thick, having a pale-green hue, and emiting a fetid odour, it was likely that the sufferer would not recover, but shortly die. Again, the sufferers from empyema and dropsies treated by incision or by the cautery, certainly perish if the pus or water be suddenly evacuated. Everyone acquainted with the history of paracentesis thoracis knows that it dates from the period of the Father of Medicine. The dogmatic statements which are to be found in the Hippocratic writings may not all be accepted without question in the present day, but it is remarkable how much truth there is in several of these. One of the highest living authorities on diseases of the chest, Dr. Walshe, commends the precept of Hippocrates, that paracentesis should not be performed before the fifteenth day of effusion, unless the accumulation of fluid be so great as *per se* to threaten life; while he questions the accuracy of the observation made in the ancient time, and adhered to pretty closely in subsequent ages, that success is less likely to follow operations where the fluid has been from the first purulent in character than where sero-albuminous ("Diseases of the Lungs," 4th edition, page 218).

The modern history of thoracentesis is very interesting. Since the writings of Trousseau in its recommendation, and the still more powerful example of our transatlantic brethren, chiefly Dr. Bowditch, the remedy has become one commonly resorted to. In the article Pleurisy, contributed to the third volume of Dr. Reynolds's System of Medicine by a physician whose premature death the profession had recently occasion to deplore, will be found an interesting account of what Dr. Anstie called a new era in the treatment of pleurisy. The new era is, however, signalised rather by the discovery and introduction of such new instruments as the suction-instrument of Dr. Wyman, so efficient in the hands of Dr. Bowditch, and the aspirator of M. Dieulafoy, than by any novel suggestion regarding the treatment of the disease. If, as is not unlikely, we have recently attained to something like perfection in the diagnosis and treatment of pleurisy, a dispassionate review of the history of the disease in ancient and modern times will justify the application of the dictum of Seneca, "Multum egerunt qui ante nos fuerunt sed non peregerunt."

It would be very easy to multiply references to important and suggestive passages in the Hippocratic writings tending to establish yet more fully the truth of the statement that the Father of Medicine was enabled, by the exercise chiefly of his most remarkable powers of observation, to acquire a really wonderful amount of accurate information regarding the causes and progress of diseases, as well as the influence exerted by various remedies over them. Enough has, however, been stated to justify Sir William Hamilton in exalting the reputation and praise of Hippocrates. Was Sir William entitled to depreciate the medical practitioners of his own time, which he surely did when exclaiming, "Has the practice of medicine made a single step since Hippocrates?" For centuries after the Hippocratic epoch, it may truly be said that little or no advance in medicine was effected. Many learned and ingenious men no doubt did appear in the ranks of the profession, and by them the position which had been achieved for medicine by Hippocrates was, at all events, maintained. In ancient times, by far the most renowned of these was Galen, who, embracing warmly the views of Hippocrates, was the first formally to expound and then systematically to formulate the doctrine of humoralism or humorism. It might be a sufficient answer to the query of Sir William Hamilton to signalise the discovery in modern days of vaccination and the introduction of sulphuric ether and chloroform as anæsthetics—the last mentioned, as the author of "Rab and his Friends" says, "one of God's best gifts to his suffering children." These were unknown to Hippocrates, and surely our possession of them indicates at least one step in advance. But we are able to point to the abandonment of many remedies altogether worthless which were used in ancient times, and to the introduction, as well as much more satisfactory employment, of others; while, owing to the remarkable and altogether indisputable progress which has been made in the prosecution, first of all, of the study of anatomy, then of physiology, and subsequently of pathology, we are justly entitled to conclude that the more advanced our knowledge of the minute structure of the body becomes, the more extensive our acquaintance with the function and uses of its several parts, and the more refined our understanding of the various morbid processes by which these are altered and destroyed, so much the more thorough and reliable will be our application and adaptation of the means of cure to the treatment of diseases. Any scientific practice of medicine before the physician had been able to acquaint himself with human anatomy was not to be expected; and it is truly marvellous that Hippocrates, Aretæus, Galen, and the Arabian physicians, notably Rhazes, were able to achieve so much, and to hand down to posterity a body of well-observed facts and careful deductions from these facts, wearing so much the aspect of science.

Medicine can, however, be said to have started on a scientific basis when Mundinus, early in the fourteenth century, applied himself with diligence to the dissection of the human body, and published a treatise on anatomy, "Anatomi Omnium Humani Corporis Interiorum Membrorum," which till the middle of the sixteenth century was the recognised textbook of the schools. The statutes of the University of Padua prescribed that all anatomical lecturers were to adhere to the literal text of the Bologna professor. Mundinus died in 1326,* universally respected; and no advances in anatomical knowledge were made after his time till Berenger of Carpi published, in 1521, a commentary upon Mundinus. There succeeded Berenger, Vido Vidius, Jacob Sylvius, and the renowned Flemish anatomist Andreas Vesalius. Of the last named, Hallam remarks that "if he was not quite to anatomy what Copernicus was to astronomy, he has yet been said, a little hyperbolically, to have discovered a new world" (Literary History, vol. i., p. 467). He was the first anatomist who ventured to emancipate himself, and that thoroughly, from the trammels of Galen, who, up to that time, had been regarded with an altogether blind veneration. Fallopius and Eustachius—two well-known names, names not to be forgotten by anyone at all acquainted with anatomy—were the contemporaries, although younger, of Vesalius; and of the same period, or shortly subsequent, were Realdus Columbus, Arantius, and Fabricius ab Aquapendente, the discoverer of the valves in the veins and the instructor of our own immortal Harvey. The splendid discovery of the circulation of the blood was followed by that of the absorbent system, in which Asellius (a professor at Pavia), Rudbeck (a professor at Upsala), and Bartholini (a Dane) were chiefly concerned; while to Pecquet, a professor at Montpellier, belongs the credit of describing the thoracic duct and its uses. Other important anatomical discoveries, and discoveries also in physiology, were being made simultaneously, or shortly thereafter, in connexion with which the names of Malpighi, Glisson, Wharton, Highmore, Richard Lower, Leuwenhœck, Ruysch, Valsalva, and many others start up. The most eminent of the pupils of Valsalva was the distinguished Morgagni, who, following the plan pursued by Bonnet in his "Sepulchretum Anatomicum," first published at Geneva, the place of his birth, in 1679, described by Haller as "immortale opus," became himself professor in the University of Padua, and was the founder of pathological anatomy ("Der Begrunder der Neurer Pathologischen Anatomie," Haeser, seite 654). His works "Adversaria Anatomica," and still more his celebrated treatise "De Sedibus et Causis Morborum per Anatomiam Indagatis," immensely advanced his favourite science.

* Mundinus, sagt John Adelphus in der von ihm besorgten Strassburger Ausgabe vom Jahre 1513, "quem omnis studentium universitas colit ac venerat ut deum."—Haeser, Lehrbuch der Geschichte der Medicin.

While chemistry, about the same time, was advancing towards the dignity of a science, chiefly through the genius of our distinguished countryman, the Honourable Robert Boyle, there arose the sect of the so-called chemical physicians. Of this sect, the earliest was François Deleboe Sylvius ("Der berühm teste Vertreter der Iatrochemischen Schule." Haeser, seite 571), who was born at Hanau in Flanders, in 1614, and, after a time, became professor of the practice of medicine at Leyden. The chemical theory of medicine had, however, passed from Paracelsus, who was born towards the close of the fifteenth century, through Van Helmont, by more than eighty years his junior, to Sylvius. The leading principles of the chemiatric physicians was that diseases owed their origin to derangement in a process of fermentation, which was constantly at work in the human body. While most of the maladies which were produced in this way arose from excess of acid, some were regarded as of alkaline origin. One eminent English physician embraced the doctrine of Sylvius. Thomas Willis was born in 1621, and in 1659 published his celebrated treatise entitled "Diatribæ duæ Medico-Philosophicæ; quarum prior agit de Fermentatione, altera de Febribus." The object of this work was to prove that in every organ of the body there existed its own special fermentation, and that diseases of every kind resulted from the disturbance of these fermentative processes. Willis was one of the earliest members of the Royal Society, and left behind him the character of an orthodox, pious, and charitable physician.* It is recorded of Dr. Willis that, being consulted regarding the delicate condition of the children of the Duke of York, afterwards James II., he spoke his mind freely, and thereby gave great offence. Bishop Burnet has related that "Willis, the great physician, being called to consult for one of his (the Duke of York's) sons, gave his opinion in the words, '*mala stamina vitæ*,' which gave such offence that he was never called for afterwards." The reputation of Willis, unquestionably a very able man, has been obscured by that of another English physician, his junior by only three years. The physician in question was Thomas Sydenham, "whose character," as Dr. John Brown felicitously remarks in that delightful essay, "Locke and Sydenham," "is as beautiful and as genuinely English as his name." He was born in Winford Eagle, in Dorsetshire, in 1624. A parallel has been drawn between Hippocrates and Sydenham by more than one modern writer. "Wiederherstellung des Hippokratismus durch Thomas Sydenham," is the title of a chapter by Haeser, the erudite German historian of medicine, and a very instructive one it is, on the life and writings of the English physician. He has frequently been called the English Hippocrates, and, in truth, the appellation is deserved; for, like the illustrious Greek physician, the great aim he set before him was the cure of disease, and although possessing a mind which delighted in speculative inquiry, he never permitted the theories he formed and ably defended to interfere with his treatment. That was based on a rational empiricism, such as we have seen in the instance of Hippocrates; he carefully watched the operation of the remedies he employed, and from these he drew the indications for further guidance. Sydenham was humoral in his pathology, and he further agreed with Hippocrates in the doctrine of crisis, and the subsidiary view as to action and crasis. We find him frequently referring to the Father of Medicine—as, for example, when he inquires what is gout? It is a provision of Nature to purify the blood of old men, and to purge the deep parts of the body; such at least is the language of Hippocrates. The same may be said of all other diseases, fully formed; and "that practice and that alone will do good which elicits the indications of cure out of the phenomena of the disease itself. This made Hippocrates divine." It was from Sydenham that the school of empirical physicians in England sprang—a term to be used, as Hallam has expressed it, "in a good sense," as denoting the regard its disciples had to observation and experience, or to the Baconian principles of philosophy.

Another school of medicine had arisen in Italy through the instrumentality of Giovanni Alfonso Borelli, a profound mathematician, who endeavoured to explain the operation of the various functions of the body on mechanical principles. His views and principles were, through the excessive zeal of his pupils, carried beyond their legitimate length. Of these, Lorenzo Bellini, of Florence and Pisa, was the chief. There were other eminent adherents of the iatro-mathematical school in Italy; while Pitcairne, Friend, and Mead, in their time, were in this country attached to it, and it secured the sympathies of the illustrious nosologist, François Boissier de Sauvages in France, in the eighteenth century.

To the chemiatric and iatro-mathematical school there succeeded a third, of which Van Helmont was the founder. Embracing the views of the former to a certain extent, he made this important addition, that all the changes occurring in the body, whether arising spontaneously or produced by remedies, are determined by a specific agent inherent in the living system, to which he gave the name of Archeus. This archeus explained, in Van Helmont's opinion, all physiological actions, and accounted for the maintenance of health as well as the occurrence of disease. Founding on the views promulgated by Van Helmont, although widely differing from him, came the earliest of the three distinguished men to whom a brief reference was made at the commencement of this address. Rejecting the doctrines of the chemical and mathematical physicians, Stahl concentrated attention on what he denominated vital actions. He, too, referred these actions to a dominating principle; and the Anima of Stahl—so he named it—resembles, in some measure at least, the Archeus of Van Helmont. To Stahl belongs the great merit of having pointed out that, contrary to the prevalent opinions of the schools, the operations of the animal economy cannot be explained by either chemical or mechanical laws, that there exists something over and above these, and that something is of the nature of vital action. The anima of Stahl, however, was a hypothetical principle, and he signally failed to gain for his theory any general support. Hoffmann, his distinguished colleague in the University of Halle, and his rival, conferred a lasting benefit on science by pointing out that the actions which were ascribed by Stahl to the government of his "anima" were in reality determined by nervous influence. "It was reserved for Hoffmann," says Dr. John Thomson, "to take a comprehensive view of the nervous system, not only as the organ of sense and motion, but also as the common centre by which all the different parts of the animal economy are connected together, and through which they mutually influence each other." Facts, and many of these most important in their nature, regarding the nervous system, had been recorded before the time of Hoffmann. The renowned professors in the early Alexandrian school, Herophilus, and Erasistratus, and Galen, with others among the ancients, Willis, Vieussens, Mayow, Baglivi, and Pacchioni, much nearer his own day, had laid the foundation for the reasoning of Hoffmann, but, as Cullen has observed, "he was the first who gave any tolerably simple and clear system on the subject, or pointed out any extensive application of it to the explanation of diseases." There is little need for reminding you of the triumphant discoveries in the nervous system which have been made since the time of Hoffmann—such discoveries as have rendered the names of Charles Bell and

Marshall Hall in particular, but many others in lesser degree, famous. In no department of pathological inquiry is there at the present time exhibited a greater amount of zeal, or are important facts being more frequently brought to light, than in that pertaining to the nervous system. How signal our advance in treatment also, as determined by that which can alone with any certainty determine treatment: a sound diagnosis! We can distinguish between functional and organic diseases of the brain, spinal cord, and nerves, and use our remedies in a way of which not only the ancient physicians, but many among the moderns, could not have dreamt.

The names of Stahl and Hoffmann, the German professors in Halle, of whom a few words have been said, are inseparably linked with that of the illustrious Dutch professor in the University of Leyden, Hermann Boerhaave. The aim of Boerhaave was essentially eclectic; he culled from the writings of his predecessors all that was valuable, and with these and the results of his own extended observation endeavoured to erect a system of medicine. His system was faulty in ascribing too little importance to the influence exerted by the brain and nervous system generally over the animal functions. The pathology of Boerhaave was as defective as his physiology; his explanations of morbid phenomena were more applicable to the body considered as an inert hydraulic machine, than as an organised living and sentient system. Intellectually and morally distinguished, few greater men than Boerhaave have adorned our profession in any age or country. After his decease, his reputation, which as a living teacher had been of the most exalted description, rather increased than declined. This result was due in great measure to the publication of commentaries on his works by two of his most distinguished pupils, Haller and Van Swieten. The former of these is justly considered as the father of modern physiology. The magnificent researches of Haller regarding development, growth of bone, and the circulation, deserve the praise and gratitude of posterity not more than the impulse of his ardent spirit and example in laborious inquiry, by which the zeal of his associates and successors was kindled. Of Haller's powerful opponent in the controversy regarding irritability and sensibility—Dr. Whytt—I can only make mention. Contemporaneously with Haller, and conferring benefits on the practice of medicine resembling those which Haller rendered to physiology, was William Cullen. A very erroneous impression of this great Scotch teacher has been entertained by many, more particularly, however, by foreigners. By such, Cullen has been called a purely speculative physician. The condemnation of this opinion is readily supplied by his own words. "There is nothing," he observes, "I desire so much as that every disease we treat here should be a matter of experience to you; so that you must not be surprised that I use only one remedy when I might employ two or three; for in using a multiplicity of remedies, when a cure does succeed, it is not easy to perceive which is the most effectual. But I wish that you may always have some opportunity of judging with regard to their proper effects." Again, he says: "Every wise physician is a dogmatist; but a dogmatical physician is one of the most absurd animals that lives. We say he is a dogmatist in physic who employs his reason, and, from some acquaintance with the nature of the human body, thinks he can throw some light upon diseases, and ascertain the proper methods of cure; and I have known none who were not dogmatists, except those who seemed to be incapable of reasoning, or who were too lazy for it. On the other hand, I call him a dogmatical physician who is very ready to assume opinions, to be prejudiced in favour of them, and to retain and assert very tenaciously, and with too much confidence, the opinions or prejudices which he has already taken up in common life, as in the study of the sciences. Now, I profess to be a dogmatist, but I should be sorry if any person thought me dogmatical, for there are but few theoretical opinions which I have received or offered to communicate with regard to disease, concerning which I am not ready to doubt, and to admit grounds for doubting, as soon as they are offered to me. I know there are no universal rules in the practice of physic, but there are general rules, which all admit of, with more or fewer exceptions, in theory and practice." The foundation of the practice of physic was expressly stated by Cullen to lie in fact and experience. "All our knowledge of Nature consists," he says, "in experience."

To Cullen we are largely indebted for the introduction into general use by medical men in this country of such remedies as the acid tartrate of potash, tartar emetic, hyoscyamus, and James's powder, or the pulvis antimonialis. Tartar emetic Cullen largely employed as an antiphlogistic, sometimes after bloodletting, and sometimes in place of that remedy. He had noticed something of the contra-stimulant action of antimony in the form of tartar emetic, described by Dr. Marryatt, of Bristol, in 1790, and afterwards so strongly insisted upon by Rasori, a professor in Pavia, and by others. A successor of Cullen, one of the most distinguished physicians in recent times, as he certainly was also one of the most benevolent of men—the revered Dr. Alison,—who occupied the chair which you, Sir, now so worthily fill, when this Association held its former meeting in Edinburgh—he, whom Dr. Stokes has recently described as "the best man I ever knew," and in so alluding to Dr. Alison, may be said to have turned many hearts towards himself; for what student knew Dr. Alison did not venerate him?—and who can ever cease to cherish his memory?—when indicating the way by which, in his opinion, the further improvement in the art of medicine was likely to be effected, signalised the two following lines of inquiry: first, in the discovery of specifics which may counteract the different diseased actions of which the body is susceptible, as effectually as the chinchona counteracts the intermittent fever, citric acid the scurvy, or vaccination the small-pox; and, second, in the investigation of causes of disease, whether external or internal—i. e., of the conditions under which either the vital action of the solids or the vital properties of the fluids of the body may become liable to deviation from their natural state. It will be readily admitted by all candid inquirers that, under the latter head, very signal advances have been made during the last half-century. Look, for example, at the etiological investigations regarding continued fevers, and the bearing of these upon treatment, with which the names of Jenner, Stewart, Bartlett, Murchison, and Buchanan are so intimately connected. Again, consider the great advances in knowledge of parasitic diseases—the entozoa more particularly,—and their appropriate treatment, for which we are largely indebted to Küchenmeister, von Siebold, Davaine, and Cobbold. Nothing more interesting or more remarkable in the line of therapeutics has recently appeared than the wonderfully successful treatment of hydatids of the lung by the internal administration of turpentine in the hands of Dr. Bird, of Melbourne, Australia.* This is a medicine in estimation of which, were time at my disposal, I could say much, having had occasion to watch its influence very closely when administered in cases of pulmonary gangrene and bronchial affections attended by copious expectoration of fetid pus. In these diseases I regard turpentine as an invaluable remedy.

Of specifics we still possess but few; while the desire to increase their number is not only legitimate, but is likely sooner or later to be gratified. Of the class of specifics no remedy better deserves the name than quinine. The potent action of quinine in intermittent fevers thoroughly justifies the application to it of the term specific; and it is to be noted that the curative action in question is to be seen not only in febrile disorders of the intermittent type, but in neuralgias which manifest a similar character. Many ingenious theories regarding the *modus operandi* of chinchona or quinine in these diseases have been advanced; but, up to the present time, we are compelled to admit that we are entirely ignorant respecting the method of action of a medicine in whose power we justly place the very highest confidence. The remarkable effects of quinine in reducing the temperature in pyrexia, and the still more remarkable influence of cold in the same way in hyperpyrexia, of which Dr. Wilson Fox has given some happy illustrations, are noteworthy facts in the recent history of therapeutics.

A remedy of marvellous power and usefulness, the virtues of which we are still only learning, is the iodide of potassium. This medicine was prepared soon after the discovery of iodine by Courtois in 1812, and has been chiefly employed as a deobstruent, alterative, and diuretic. I am satisfied that the diuretic properties of iodide of potassium deserve to be more widely recognised than is generally the case. Its specific action is seen in syphilitic periostitis, for truly the rapidity and completeness with which pain and swelling decline and disappear in instances of enlargements over the tibiæ and other bones in cases of secondary syphilis are not less remarkable than the readiness with which an attack of intermittent fever or neuralgia yields to quinine. The late Dr. Todd, of London, remarked: "If there is anything in addition to quinine which deserves the name of a specific, it is the iodide of potassium in syphilitic periostitis." Another remarkable action of this medicine is in aortic aneurism. Iodide of potassium, administered for the most part in tolerably large doses, in this terrible disease exerts a wonderful influence, not only in relieving the neuralgic pains, which are frequently so harassing, but in subduing the local pressure occasioned by encroachments of the aneurism, and in leading, apparently, to firm coagulation within the sac.

---

* Dr. Bird had formerly used bromide of potassium, twenty grains, with one fluid drachm of tincture of kamela in infusion of serpentary, three times a day regularly. (On Hydatids of the Lung. Melbourne, 1874.) I am, however, assured by a recovered patient that, in the treatment of pulmonary hydatids, Dr. Bird now places great reliance on turpentine administered internally.

It is in the treatment of thoracic aneurism by iodide of potassium that physicians have learned the very remarkable tolerance of the drug manifested by sufferers from that disease. No reasonable suggestion has hitherto been offered regarding the *modus operandi* of iodide of potassium in aneurism. The influence it exerts on the progress of aneurism appears to have been discovered not only empirically, but by the merest hazard, writes Dr. Walshe; "in this point of view, the story of all our really valuable medicines is simply repeated" ("Diseases of the Heart," fourth edition, page 512). The names of Bouillaud, Nélaton, and Chuckerbutty are specially connected with the early employment of the iodide of potassium in the treatment of aneurism; while the profession is largely indebted to Dr. G. W. Balfour, of Edinburgh, for his patient investigation into the subject. (*Edinburgh Medical Journal*, 1868.)

Twenty years ago little was known regarding the virtues of bromide of potassium. If any standard work on the materia medica of that date be consulted, it will merely be found recorded of this salt that it is diuretic and cathartic, and, like the preparations of iodine, a powerful deobstruent and alterative. Its dose, moreover, is stated, in such works, at from three to twelve grains thrice daily. Since then, and more particularly within the last few years, bromide of potassium has rapidly advanced in professional estimation; and, at the present time, it may with confidence be affirmed that there are very few medicines which are more largely employed, and the use of which is attended by more signal benefits. As a calmative and hypnotic, bromide of potassium is largely confided in; but its specific operation in epilepsy is of the most striking description. "It is to be demonstrated, in my opinion," writes Dr. Russell Reynolds, "that there is something specific in the action of bromide of potassium in epilepsy." And the same author observes: "Bromide of potassium is the one medicine which has, so far as I know, proved of real service in the treatment of epilepsy." My own experience of the use of bromide of potassium in epilepsy has been of the most encouraging description. I have repeatedly witnessed cures, in the strictest sense, result from its employment. Let me briefly refer to one such.

S. A——, a bookbinder, aged fifty, had for twenty years been subject to severe fits, occurring irregularly by night and by day, often attended by biting of the tongue. The usual interval between the fits had been a fortnight, and on no occasion had a longer period than six weeks elapsed. In January, 1870, this patient, whose mental capacity had at that time become considerably enfeebled, so much so as to make it necessary for him to give up his business, began the bromide of potassium, and continued it for eighteen months without any pause. The dose never exceeded twenty grains thrice daily. The result of this treatment was an entire cessation of the epilepsy; and there has been no recurrence of the disease. His mental vigour has returned. He long ago resumed his occupation, and has since been busily engaged in it without any interruption.

I could multiply instances of this kind; and so, I believe, could many practitioners who, in the treatment of epilepsy with bromide of potassium, have been mindful to adhere to the rule upon which Dr. Reynolds insists, that the remedy "should not be discontinued in the treatment of a case of epilepsy because of its apparent failure, but that the dose should be gradually increased, and the exhibition of the drug most patiently carried on for a period of many months, or even years." Epilepsy is a disease which specially attracted the attention of the ancient physicians. It was termed *νόσος ἱερὰς*, the sacred disease, by the Greeks; and Aretæus expressly mentions why the appellation "sacred" was given to epilepsy: "for more reasons than one," he remarks—"from the greatness of the evil, for the word *ἱερὸς* also means great, or because the cure of it is not human but divine, or from the notion that the disease occurred from the entrance of a demon into the man." Plato, in the "Timæus," ascribes the use of the term "sacred" to the circumstance of the head or brain being the part of the body affected in epilepsy. "When the phlegm is mingled," he says, "with black bile, and dispersed about the courses of the head, which are the divinest parts of us, and disturbs them in sleep, the attack is not so severe; but when assailing those who are awake, it is hard to be got rid of; and, being an affection of a sacred part, is most justly called sacred." Hippocrates combated the notion entertained by his countrymen that epilepsy was peculiarly a sacred disease, one specially inflicted by the gods. In the treatise *Περὶ Ἱερῆς Νούσου*, he emphatically points out that the incomprehensible nature of the malady is no reason for concluding it to be divine, inasmuch as many other diseases, and notably the paroxysms of intermittent fevers, are just as much above the reach of the human understanding. He believes that epilepsy, like other diseases, results from natural causes. The reader of the remarks on epilepsy in the pages of Hippocrates and Aretæus cannot fail to have his opinion of these great men enhanced; but he also cannot fail to reach the conclusion that the moderns, understanding the nature of convulsive diseases, their connexion with altered conditions of the blood—with, for example, anæmia and uræmia,—and their dependence at one time on central, at another on peripheral irritation of the nervous system, are infinitely better prepared for their treatment than they were; and this unquestionably holds true of epilepsy.

The use of the remedies we have been briefly reviewing has, in the first instance, been adopted either by mere accident or empirically; nor have we, on this account, any cause for feeling regret. We do not know in what the preservative power of vaccination consists; and yet millions of lives have already been saved by this precaution (Œsterlen). A recent and very interesting example of the way in which therapeutical knowledge may be advanced is afforded by what has occurred in the Andaman islands. Dr. Dougall, a distinguished graduate of the University of Edinburgh, has apparently discovered that leprosy sores and other ailments attendant upon that disease can be cured by the aid of the Gurjon tree, which is very common in these islands. Take another disease known to the ancients, although its pathology, still to a considerable extent obscure, has been carefully investigated only in recent times—I mean diabetes; and regarding it, we may compare the treatment pursued by Aretæus, for example, and that which we now employ, with the result of feeling thoroughly assured that many steps have been taken in the right direction, and with signal advantage to suffering humanity, since the writings of the distinguished Cappadocian physician. I do not think the opinion unfounded that, owing to the recent advances in the knowledge of tubercular diseases, etiologically and pathologically, we may look forward with confidence to a decided gain in their efficient treatment; but even now may we not be said to possess in cod-liver oil a very potent means of modifying the progress of pulmonary tuberculosis? In the treatment of this disease and of other allied constitutional disorders, cod-liver oil was first employed in the Manchester Infirmary, chiefly by the elder Bardsley, after the commencement of the present century. Previously to that time, however, an oil obtained by ebullition with water from the fresh livers of several fishes, the ling and skate as well as the cod, had long been a domestic panacea in strumous affections and chronic rheumatism. Subsequently to its use in the Manchester Hospital, cod-liver oil was largely used in Germany; but, falling into disuse in this country, its restoration to professional and public favour has followed the publication of Dr. Hughes Bennett's recommendation of its virtues, in his excellent treatise on that subject. Sir Thomas Watson has very happily expressed the characteristic effect of the remedy in phthisis, when he says: "It is antagonistic to a much greater extent than any other drug of the consuming power of the disease." There are probably few medical men who have seen much of this sad malady who would hesitate to concur in the opinion of a very high authority—Dr. Williams—that cod-liver oil is more beneficial in the treatment of pulmonary consumption than any other agent, medicinal, dietetic, or regiminal, that has yet been employed. We may justly congratulate ourselves on the possession of cod-liver oil, but it becomes us to remember that the ancient physicians used oil inunction in phthisis. This is expressly stated by Aretæus, and he, as well as Hippocrates, lauds the use of milk in the same disease, preferring it to all other kinds of food. "For," says the former, "milk is pleasant to take, is easy to drink, gives solid nourishment, and is more familiar than any other food from childhood. In colour it is pleasant to see, as a medicine it seems to lubricate the windpipe, to clean as with a feather the bronchi, and to bring off phlegm, improve the breathing, and facilitate the discharge downwards. To ulcers it is a sweet medicine, and milder than anything else. If one will, then, only drink plenty of milk, he will not require anything else. For it is a great thing that in a disease milk should serve both for medicine and nourishment." In fevers Hippocrates did not allow milk, more particularly in such fevers as were attended by bilious discharges from the bowels. The modern practice is not in this very important particular in agreement with the ancient, the highest authorities, as, for example, Gairdner, Murchison, and Parkes—the last-mentioned on weighty theoretical grounds—considering milk the best food in fevers.

We have been alluding to the manner in which the practice of medicine has been advanced, and may doubtless be still further advanced, by the simple method of observation and experience. It is true that we cannot entirely depend upon empirical laws. We cannot, for example, feel assured that quinine will certainly cure an attack of intermittent fever, mercury syphilis, or, for that matter, that a dose or doses of any given medicine will exert their thoroughly ascertained physiological or therapeutic action; still such laws are of the highest value, and we cannot help employing them.

The recent progress of chemistry, physiology, and pathology, has naturally led to the establishment of an advanced school of therapeutics, from whose labours signal benefits may not only be anticipated for medicine, but have already been conferred upon it. To Dr. Lauder Brunton, for example, belongs the great merit of distinguishing accurately the therapeutic action of the nitrite of amyl from its physiological properties, and thereby of adding a useful remedy to our armamentarium. And so, also, to Dr. Fraser we are indebted for the elaborate investigations regarding the Calabar bean, which have resulted in a demonstration of its therapeutic value. Care must, however, be taken that the results of scientific inquiry and those of patient, oftentimes laborious, observation in the field of practical medicine running counter, do not interfere with the ultimate grand object of our profession—the healing of the sick.

We are not entitled to withhold remedies because we do not understand their exact nature, nor the minute changes they produce in the animal economy. Œsterlen has well expressed the attitude which, as practitioners of medicine, we are called upon to assume. "The patient requires our aid, and we must decide for or against the employment of a particular medicine, and upon the manner in which to employ it. If we possess sufficient experience, knowledge of the subject, and practical tact, we shall no doubt be able to do all for that patient which circumstances permit."

Let each one of us be fully persuaded in his own mind. While deeply interested in, and much instructed by, the experiments performed by a Committee of this Association, regarding the use of mercury for example, I remain as thoroughly convinced as ever that the much-abused drug in question exerts a powerful action on the function of the liver, and is to be trusted as a most efficient remedy in controlling not a few of its disorders.

I regard cold as a powerful antiphlogistic, and its external application, already briefly referred to, as a remedy of unquestionable value in the treatment of hyperpyrexia; but my own observation, and the fullest attention I have been able to give to the recorded observations of others, have convinced me that the real reason for the present abandonment of a remedy of superior power—to wit, bloodletting—does not lie alone in the advance of scientific pathology. "The thinking man," writes one of the most philosophical of living physicians, Dr. Stokes, "finds it hard to believe that the fathers of British Medicine were always in error, or that they were bad observers and mistaken practitioners. They, indeed, have rested from their labours, but their works remain; and he who reads the writings of Sydenham, of Haygarth, and of Fothergill, of Heberden and Fordyce, of Gregory, Cullen, Alison, Cheyne, or Graves, must have a very inapprehensive mind if he fail to discover that there were giants in those days, and that the advocacy of such ideas only indicates a state of mind not consonant with the modesty of science."

Clinical Lecture
ON
CONVULSIONS
DUE TO MORBID CONDITIONS OF THE UTERUS IN THE NON-PUERPERAL STATE.

Delivered in University College Hospital,

BY GRAILY HEWITT, M.D., F.R.C.P.,

PROFESSOR OF MIDWIFERY AND DISEASES OF WOMEN IN UNIVERSITY COLLEGE, ETC.

GENTLEMEN,—In regard to the connexion between certain morbid conditions of the uterus in the non-puerperal state and the occurrence of convulsions, the subject to which I intend to direct your attention on this occasion, it may be said that comparatively little of a positive character is known. You are well aware that convulsions may be produced in two principal ways, and they have accordingly been divided into two classes—namely, centric and eccentric. The convulsions produced by the uterus come under the latter category; they are eccentric.

In considering this subject, let me remind you, in the first place, of the fact, very well known, that the sympathy existing between the nervous system of the uterus and the general nervous system is of the most intimate possible character. Of that we have abundant evidence. A remarkable instance of this is the fact that in the course of labour, if the patient be frightened, the labour may be altogether arrested for a time; and, conversely, a sudden fright may be the means of bringing on the process of labour. Again, sickness, a frequent attendant on pregnancy, is a sympathetic result of the condition then present. Sympathetic "uterine" sickness may occur also at other times, for it may be produced by certain morbid conditions of the uterus. It is, in short, one of the most common symptoms of uterine disease.

The occurrence of convulsions, as due to the uterus in the non-puerperal state, must be set down to the existence of some irritation in the uterus itself, this irritation acting in a reflex manner. The fact that the uterus itself can, in the non-gravid condition, give rise to convulsions is, it may be said, one which is not generally received and admitted. And, further, in quarters where so much as this is received and admitted, it has not yet been pointed out what is the nature of that irritation in the uterus which can and does give rise to these convulsions. This subject has for a long time occupied my attention, and having seen a considerable number of cases, I feel now in a position to express a very decided opinion upon it. I entertain the belief that there is a very well established connexion between the occurrence of convulsions and the existence of certain morbid conditions of the uterus.

The convulsions of which I am about to speak include those convulsive attacks which are ordinarily known and spoken of under the term of hysterical convulsions, and they include certain other cases of convulsions which lie in a sort of intermediate position between the hysterical and the true epileptic convulsions, and which may, for the want of a better term, be spoken of as epileptiform. But the great majority of these cases are such as have been distinguished as hysterical. I do not intend, on this occasion, to discuss the general question of hysteria, but simply to deal with the convulsive attacks observed. A case recently under my observation in this hospital will form the text of my remarks, which will be limited to the facts noted in this particular case.

CASE.—*Acute Anteflexion of the Uterus, probably of one year's duration; Convulsive Attacks occurring frequently during that time.*—The case more fully reported is as follows:—L. F——, thirty years of age, admitted Nov. 15th, 1874. Married six years; has had one child only, four years and a half ago; no miscarriages. Respecting the family history, it is stated that her mother is alive, and has had a paralytic seizure, from which she has recovered. The patient was always delicate, but enjoyed fairly good health until the present illness. The catamenial discharge was pretty regular until three months ago, since which time it has not appeared. Quantity generally above the average. It was not attended with pain. Her health was good until twelve months ago. About this time the patient was engaged for some six weeks in nursing and closely attending upon her sick child; she attended it both day and night. To the nursing of the child and this considerable bodily exertion the patient attributes her illness. The illness began very shortly after the recovery of the child. It commenced with an attack which was denominated a "fit." This came on in the morning. She lost her consciousness for a second, was convulsed, and, on recovery, ran in a state of alarm into an adjoining room. Since that time, except an interval during last summer, she has had fits occurring once, twice, or three times a day, lasting for a brief space, and not generally accompanied with loss of consciousness. For a moment or two after the attacks her eyes are affected, and she "sees things before her eyes" and has "dreadful things on her mind." Sometimes she is unable to see for a few minutes. She does not fall down during the fit, nor does she bite her tongue. The fits occur most frequently at night. Lately, since menstruation has ceased—that is to say, for the last three months,—the fits have become more intense. She has somewhat emaciated. A short time after the commencement of her illness she was under treatment at another hospital, where the attacks were pronounced to be epileptic. Since menstruation has ceased there has been more or less leucorrhœal discharge, sometimes puriform in character; and this was observed first when menstruation should have occurred, but did not. For the last few weeks she has felt shooting pains in the left groin. A walk across the room is attended with difficulty. Intercourse gives rise to pain. A few days after the admission of this patient into the hospital, on November 18th, the catamenia returned, after three months' cessation, and continued for two days.

Up to the time of my first examining the patient (Nov. 30th) there had been no alteration in regard to the occurrence of the convulsive attacks, which, as I before remarked, occurred one, two, or three times in the course of twenty-four hours. On Nov. 30th I first made the examination, and on that occasion it confirmed the result of an examination which had been previously made by Dr. Williams and by the obstetric assistant. The result was that the uterus was found anteflexed. The uterus was large, anteverted, and extremely anteflexed, the fundus being low down between the cervix and the pubic bones. By the aid of the sound, the introduction of which was extremely difficult, in consequence of the sharpness of the bend of the uterus, the uterus was restored to its natural position. It may here be mentioned that the patient herself had supposed that she was pregnant, but it was not so. The diagnosis was expressed in the following terms:—In consequence of severe and long-continued exertion in nursing her sick child, the patient became the subject of anteflexion of the uterus; the anteflexion had since progressively increased in intensity, and the attacks of convulsions, together with the arrest of the catamenia, are due to this condition of the uterus. Up to this time, as already remarked, since the patient entered the hospital the fits had continued as frequently as before admission. After replacement by the sound the uterus was treated by inserting a cradle pessary, so as to elevate the fundus uteri, and to maintain it in that elevated position. The satisfactory accomplishment of this object, the elevation of the fundus uteri, was more than usually difficult in consequence of the size which the fundus of the uterus had attained.

The subsequent history of the case is as follows:—Dec. 1st: No fits in the night; one this morning, but less severe.—2nd: Five slight fits during the night.—3rd: Two slight fits this morning; severe pain in left groin last night, and this morning catamenia reappeared.—4th: No fits or peculiar sensations; catamenia continues.—5th: A slight fit yesterday afternoon, also two slight ones in the night.—6th: No fits.—7th: No fits.—8th: One in the night.—9th: No fits. 10th: One fit and two "peculiar sensations" last night. 11th: No fits.—12th: No fits.—13th: One fit last night. 14th: No fits.—16th: "Peculiar sensations" last night. 17th: Ditto.—18th: One fit.—19th: No fits.—20th: Two "peculiar sensations."—21st: Ditto.—22nd: One rather severe fit with "sensations."—24th: No fits.—27th: No fits or sensations.—Jan. 5th, 1875 (twelve days since the last report): A bad fit last night.—9th: Catamenia returned.—13th: Catamenia continues, discharge very profuse, and coming in gushes.—15th: Period ceased, and the patient was allowed to get up, having been kept in the horizontal position until this time.—18th: Not quite so well; had a fit this morning; has been up each day for the last three days.—19th: Another fit this morning.—21st: No fit for two days.—22nd: Discharged.

During the whole of the patient's stay in the hospital the only treatment to which she was subjected was the use of the sound on one occasion, the wearing of the "cradle" pessary, and the maintenance of the body in the horizontal position. The legitimate deduction to be drawn from the foregoing statement is, that the treatment adopted had a very decided influence in alleviating the principal symptom—viz., the convulsions—from which the patient was suffering. There can be very little doubt of that. Before the time of the commencement of the treatment the fits occurred frequently every day, while under this treatment they were not altogether abolished, but very much lessened in degree and frequency. The treatment virtually consisted in straightening the uterus. The mechanical appliance used had the simple effect of preventing the descent of the fundus uteri anteriorly, the organ being thereby straightened.

In the next place, I will proceed to explain what I believe to be the connexion between the malady in question and the occurrence of the convulsive attacks. The case was one of very acute anteflexion of the uterus. When the uterus is actually bent on itself, as in this case, one physical result is inevitable—namely, that the tissues of the uterus are excessively compressed, especially on the concave side of the bend. The thickness of the uterine wall at the situation where the bend ordinarily occurs—viz., at the junction of the cervix and the body, corresponding to the internal os uteri—is not so great as above that point, but still it is considerable. The tissues of the uterus at this situation necessarily undergo compression, as the result of the acute flexion which is present under these circumstances. The result is that the blood is forced out of the tissues of the uterus at the situation in question by the action of this compressing agency. And inasmuch as the uterus is everywhere pervaded by nervous filaments, these delicate structures become also subject, like the other tissues of the organ, to forcible compression. In proportion as the flexion becomes increased in intensity so does the compression increase in degree. It is this compression of the nervous filaments of the uterus which constitutes, in my opinion, the irritation of the uterus which gives rise to the symptoms in question, and which, in fact, produced the convulsions in the particular case above described. It is one of the facts in this case that the fits were often worse at night. This is to be accounted for, I believe, by the change in the position of the uterus produced by the recumbent posture. Another explanation may be given of the connexion between the flexion and the occurrence of convulsions, and it is this: that inasmuch as the fundus of the uterus becomes acutely congested from time to time, as the result of this flexion, the convulsions are produced by and as the result of that acute congestion. It would be quite reasonable to suppose that acute congestion of the fundus of the uterus might cause such irritation of the organ as to give rise to convulsions. One of the most important effects of flexion of the uterus is the occurrence of congestion of the two extremities of the uterus, the fundus and cervix uteri. Doubtless, in this very case such congestion was present, and was intensified from time to time by the change of position of the patient. I, however, entertain the belief that the compression of the nerve-tissues, as well as compression of the tissues of the uterus generally, is really the starting point of the irritation which exists.

It has been a maxim with almost all writers and observers who have been really acquainted with diseases of the generative organs in the woman, that marked hysteria is connected in some way with disease of the uterus; but the precise nature of that uterine disorder, and the mechanism of the process by which the symptoms are produced, have never been satisfactorily described. My own observation has led me to the conclusion that marked flexion of the uterus exists in all cases of severe repeated hysterical attacks. This is the theory I advanced in the last edition of my work on Diseases of Women, published in 1872. At this moment I desire, however, to limit myself to the consideration of the nature of the convulsive seizures incidental to hysteria.

Respecting the truth of the theory now put forward confirmatory evidence is by no means wanting. Niemeyer, whose facts are generally considered as reliable, and who was certainly not disposed to attach an undue importance to these special uterine disorders, says that flexions, more than any other of the disorders of the uterus, give rise to hysteria. This is an exceedingly valuable statement, coming as it does from a distinguished modern pathologist. It is, in fact, a piece of evidence from the opposite camp, so to speak, and is important as bearing out my view of the case. The further arguments I submit are as follows:—In the first place, there is the *à priori* argument. It is reasonable to suppose that compression of the uterine tissues, involving as it must do compression of the nervous filaments, may produce such irritation as to give rise to convulsions. It does not, however, at all follow that such compression will always produce convulsions. It would be as reasonable to find fault with the theory that convulsions are sometimes due to the presence of worms in the intestinal canal, because these entozoa do not invariably give rise to convulsions. No one, however, doubts the connexion between these two events. It is therefore not a sufficient reply to this statement to say, that if this theory were true convulsions would always occur when compression of the uterine tissues is produced. The clinical arguments in favour of this view seem to me to be overwhelming. I have seen a considerable number of cases in the course of the past few years where convulsions of the kind described have actually ceased when the flexed uterus was so treated as to diminish or remove the compression existing at the seat of the flexion. And in all such cases I have observed that this kind of treatment produced a very marked effect even when it did not succeed in at once removing the attacks. This is an important argument. Another is, that the position of the body, or any exertion which has a tendency to aggravate the flexion, invariably aggravates and intensifies the convulsions. I could relate many instances where this interesting fact was observed. Thus, in one case of severe retroflexion, giving rise to convulsions, the attacks instantly ceased when the patient was made to lie on her face, this improvement being in that case effected without any other mechanical treatment of the uterus whatever. In another case, that of the wife of an Indian officer, in whom the convulsive attacks were produced by anteflexion of the uterus, they invariably occurred when the patient was sitting upright at the dinner table, that being the only time of the day when they did occur. The sitting position increased the anteflexion, and thus gave rise to the convulsions. These are typical instances, but I could mention several such cases. A further argument is the effect of measures having a more direct curative action upon the flexion, and which have been employed with the idea of restoring the uterus to its proper shape. I mean the employment of the sound and the use of pessaries in order to restore the uterus to its true natural shape. I now state that the effect of these measures has been, clinically, to give proofs, over and over again, of the validity of the position which has been taken up, inasmuch as the convulsions, or the tendency to convulsions, have always been influenced favourably in direct proportion to the degree in which the flexion has been favourably acted upon. Another argument which I have to submit to you is the result of very careful exploration of the uterus in many of these cases, an exploration made by the finger and the sound. It will be found in these cases that the introduction of the sound, if properly managed, gives no pain to the patient until it reaches the situation where the flexion exists. When the sound has been introduced a distance of one inch into the cervical canal its point comes in contact with that part of the uterine wall which is the seat of the compression; and invariably it is found, under these circumstances, that the patient experiences very great pain when that part is touched by the point of the sound. After the point has passed through this strait, and when passed beyond the site of the flexion, there is no more pain felt by the patient. But the mere touch of the point of the sound on the uterus in this situation always gives rise to extreme pain and evidence of extreme sensitiveness. It requires that the examination should be conducted with great care in order to give this result, because it generally happens in these cases that the uterus as a whole is also sensitive to the touch. But by carefully conducting the examination you will be able to define those parts which are so very sensitive to the touch.

This theory, which has now been brought under your notice, that the convulsive seizures in the case above detailed and in similar cases are traceable to the compression of the tissues of the uterus, is not, then, a fanciful one; it rests upon observations made carefully and repeatedly. And it is quite certain, to my mind, that its truth will be confirmed by all careful and unprejudiced observers. The uterus is in its normal and healthy condition very little sensitive to the touch, and little liable to give rise to reflex disturbances; but the clinical evidence is to the effect that its sensitiveness to the touch, and what may be termed its "reflex sensitiveness," are very much increased by compression arising from the alteration of the shape of the uterus, and especially that alteration which is now so generally known under the term of flexion of the uterus. These reflex disturbances are many in number, and the liability to convulsive attacks is simply one of them. The case which has been brought before you is one of anteflexion, but I have seen very severe convulsive attacks occur in cases of retroflexion, and it appears that they are liable to occur in a more *severe* form in cases of retroflexion. The degree of the flexion is liable to be greatest in cases of retroflexion, and hence the severity of convulsions due to it will be greater than in the case of anteflexion.

Time will not permit me to enter on the details of treatment applicable to such cases as the above, but I have endeavoured to give sufficient indications as to the principles which must constitute the basis of the treatment.

ON ANÆMIA.

BY JULIUS POLLOCK, M.D., F.R.C.P.,
SENIOR PHYSICIAN TO CHARING-CROSS HOSPITAL.

THE disease which we call anæmia, more or less incorrectly, but for which perhaps it would be difficult to find a more appropriate name, may be the result of a number of different causes. I do not propose now, however, to consider more than one form of anæmia—that which we meet with so frequently amongst young unmarried women, and which generally occurs in connexion with some disordered state of the menstrual function. In such cases the catamenia are usually irregular in their appearance, frequently absent for months together, the discharge pale and scanty when it does occur, lasting sometimes but a few hours.

The relation of anæmia to amenorrhœa, pathologically, is of some interest. Is the latter due to the poverty of the blood? or is the formation of red corpuscles in some way discouraged by the irregular performance of the uterine functions? Doubtless anæmia, however produced, frequently gives rise to a scanty and infrequent catamenial discharge, as we see in advanced phthisis, and other wasting and blood-spoiling disorders. But is the converse true? Will functional irregularity of the monthly periods, when continued for any time, produce anæmia? I believe it will. There is some reason to suppose that the menstrual discharge is, to a certain extent, an excretion; and possibly its absence may lead to the retention in the blood of some material hostile to the formation of red-corpuscles. We certainly see cases of young girls who have enjoyed good health and looked well up to the period of puberty, in whom anæmia has gradually occurred in consequence of the non-appearance of the catamenia at their proper time; and the accidental stoppage of the courses in a healthy young woman, from exposure to wet and cold at an unfortunate time, or from some shock to the nervous system, will often, if the function remain suspended any time, lead to anæmia. But I do not think that the disorder is produced in these cases so much (if at all) by the retention of some morbid matter in the blood, as by the disturbing effect upon the nervous system of the absence or irregular performance of an important sexual function.

When this form of anæmia is allowed to go on without proper treatment, the patient ultimately presents an almost blanched appearance, the skin having a sickly green tint; hence the term "chlorosis." The lips and the cheeks are usually as pale as the forehead, but the face not unfrequently has an unnatural flush, which might deceive the inexperienced. The conjunctivæ are of a pearly white, sometimes of a slightly yellow hue, which must not be mistaken for jaundice. It is a wonder how such persons can get about or do anything, and, in truth, they are not fit for much. Upon the slightest exertion, and especially on going upstairs, they suffer from palpitation of the heart and breathlessness. They often feel faint, giddy, and sick; complain of pain in the left side, indigestion, loss of appetite; the bowels do not act well, the tongue is furred, and the breath foul; towards evening the ankles become puffy and swollen; a soft systolic bruit may frequently be heard over the base of the heart, and in the veins of the neck the stethoscope will detect the so-called "humming-top" murmur or *bruit de diable;* but it must be remembered that this latter sound may be sometimes produced in a healthy person by the mere pressure of the stethoscope. Anæmic women are generally more or less nervous, and sometimes hysterical, but I should not say there was any marked connexion between anæmia and hysteria.

How are these cases to be treated? Clearly by so nourishing the blood as to build up the red corpuscles and raise them to the proper standard in health. Steel is the medicine upon which we chiefly rely to effect a cure, but to be successful in the treatment requires some care and discrimination. If the tongue is coated and the digestion much impaired, the more astringent forms of iron, such as the sulphate or the perchloride, are often not tolerated at first; and the ammonio-citrate, the mistura ferri co., or the ferrum redactum, will be the best to begin with. In a large number of cases I have found nothing so successful as a combination of the ammonio-citrate of iron and rhubarb in suitable doses, with equal parts of some bitter infusion and peppermint-water. Sometimes the addition of two or three grains of the carbonate of ammonia seems to be useful. I make rather a point of the rhubarb, although it is so disagreeable to take, as I believe it much assists the action of the steel, especially when the stomach is out of order. If the patient is very nervous, ten grains of the bromide of potassium may be added with advantage to each dose of the mixture. If the rhubarb in the mixture does not act enough upon the bowels, it will be necessary to prescribe some aperient pill to be taken at bedtime. Preparations containing aloes are of service, and may be combined with steel. Pepsine is often useful with the meals. The diet should be light and simple; beer had better be avoided in most cases, and a glass or two of light claret may take its place with advantage. I believe claret is certainly better than port, although that wine is so often recommended. A moderate amount of exercise out of doors, when the weather permits, should be insisted upon, but anything like fatigue must be avoided. A tepid bath in the morning and a rub down afterwards with a rough towel is a good thing. By and by, in a few weeks, more or less, the steel and rhubarb mixture may be left off, and fifteen drops of the solution of perchloride of iron given after each meal in a wineglass of water.

Under the very best and most careful treatment, the improvement in anæmia is not unfrequently slow and tedious, and, to prevent disappointment, it is as well to caution patients and their friends that they are not to expect, as a rule, any very rapid change. Once get the patient on the road to health, however, and time and perseverance will do the rest.

Harley-street, Cavendish-square.

CASE OF ANEURISM OF THE ANTERIOR COMMUNICATING ARTERY.

By T. W. McDOWALL, M.D. Edin.,
MEDICAL SUPERINTENDENT OF THE NORTHUMBERLAND COUNTY ASYLUM.

This case appears worthy of record on account of the position of the tumour. Although I have now examined the brain in several hundred cases, chiefly among the insane, it never was my good fortune to meet with a specimen of aneurism of any of the cerebral vessels except the one to be now described. Any remarks which it may be considered necessary to make shall be reserved until the history and post-mortem appearances have been given.

A. B—— was admitted into the Northumberland County Asylum on October 16th last. She was at that time sixty-nine years of age, a widow, and said to be labouring under her first attack of insanity, which had existed for "some weeks." The cause of her illness was unknown. She was not epileptic, but was considered suicidal and dangerous. She was certified as being restless, always unhappy, and ever suspicious of those about her; memory greatly impaired; imagining that some one has robbed her, and disposed of her property; she has attempted several times to throw herself before passing trains.

Upon examination, on admission, she was described as slightly below the average height, fairly muscular, rather corpulent, complexion sallow, eyes grey, hair fair, temperament phlegmatic, expression vacant and demented. Circulatory system: Pulse 80; arteries at wrist atheromatous; no cardiac murmur. Respiratory system normal. Digestive system: Tongue clean; bowels regular; appetite pretty good; she states that everything she eats has a nasty, bitter taste. Genito-urinary system normal.

Mental condition.—This is evidently a case of dementia, though there are delusions of suspicion. She with difficulty understands the simplest questions, and is very incoherent in her answers. Her memory is very defective, especially concerning recent events. There is considerable depression of spirits and listlessness of manner. She states that she has been robbed of money by pitmen entering her house at night.

The following notes will show the progress of the case, which during life presented no special features of interest.

Oct. 17th.—In conversation she always reverts to the pitmen having plundered her house. So far she has conducted herself well, and attended to the calls of nature. Appetite good; bowels regular.

19th.—She is cheerful and apparently contented, but quite demented and childish in manner and conversation. Sleeps well.

22nd.—Still labours under the delusion that her house is being robbed. Takes her food well, and is otherwise unchanged.

Nov. 13th.—There is no change in her mental condition, but her bodily health and condition appears rather feeble.

Dec. 2nd.—She is decidedly more demented; her memory is much worse, and her conversation quite unintelligible.

Jan. 4th.—Deterioration progresses; she has become filthy in her habits. Water enemata were tried on three occasions, in the hope that her habits would be improved, but the result was not satisfactory. Her bodily condition is markedly worse.

Feb. 10th.—No decided change in mental or bodily condition since the date of last entry. The appetite continues fair, bowels regular.

March 9th.—She has a slight attack of bronchitis. To be kept in bed. Ordered milk, beef-tea, and four ounces of whisky daily. Pulse 90, very feeble.

16th.—Bronchitis has disappeared; a small bedsore is coming over sacrum. Patient to sit up in a carpet chair for a few hours daily. She is now in a very feeble and helpless state, dirty in her habits, and requires constant attention.

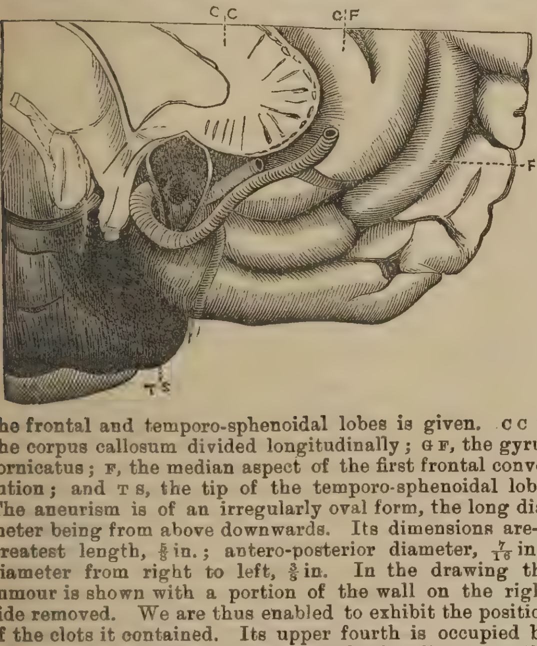
24th.—Bedsore over sacrum is enlarging and deepening, in spite of most careful nursing.

April 14th.—She is now confined to bed during the whole day, becomes more and more feeble, and the bedsore is in a sloughy condition. Liberal diet and stimulants continued.

19th.—Worse in every respect.

21st.—Died to-day.

Autopsy, thirty hours after death.—Weather warm. Body free from bruises and other marks of injury, but there is a large bedsore, and a small ulcer on each leg. The body is fairly nourished. No rigor mortis. — Head: Calvaria of average thickness; dura mater adherent in frontal region. During removal of brain, a large quantity of fluid—several ounces—escaped. There is no thickening or opacity of the arachnoid, but the amount of subarachnoid effusion is very great. The vessels at the base, and all the large arteries throughout the brain, are very atheromatous. All the convolutions in the frontal and parietal regions are atrophied, but the third parietal on each side is the one most affected. The membranes strip with great facility. On section, the grey matter is found pale and much atrophied, and the white is dirty in appearance. On a level with the corpus callosum, in each centrum ovale, there are numerous—about twelve—minute points of yellow softening. The lateral ventricles contain but a small quantity of fluid; their lining membrane is normal. Upon separating the hemispheres, and lying immediately in front and above the optic commissure, is an aneurism of the anterior communicating artery. The size, position, and relations of the tumour are represented, after a fashion, in the subjoined rough sketch. The internal surface of a portion of the frontal and temporo-sphenoidal lobes is given. C C is the corpus callosum divided longitudinally; G F, the gyrus fornicatus; F, the median aspect of the first frontal convolution; and T S, the tip of the temporo-sphenoidal lobe. The aneurism is of an irregularly oval form, the long diameter being from above downwards. Its dimensions are—greatest length, $\frac{5}{8}$ in.; antero-posterior diameter, $\frac{7}{16}$ in.; diameter from right to left, $\frac{3}{8}$ in. In the drawing the tumour is shown with a portion of the wall on the right side removed. We are thus enabled to exhibit the position of the clots it contained. Its upper fourth is occupied by a firm clot, of a dark-red colour, and firmly adherent to the wall of the sac. A small clot projects into the cavity on its left side, about the middle, marking the orifice of communication between the left anterior cerebral and the anterior communicating arteries. In the drawing, the continuation of the *right* anterior cerebral artery is seen to spring, as it were, from the posterior part of the aneurism. Once free from the tumour, both anterior cerebral arteries pursue their usual course, as may be seen in the drawing, where for convenience only a short portion of them is represented. The walls vary much in thickness, and are of a dense white appearance—indeed, exactly like what is usually seen in atheroma of any of the cerebral vessels. By pressure the tumour has made room for itself in the surrounding cerebral tissue, but has not caused softening or other morbid process. — Thorax: The pericardium contains about two drachms of yellow serum. Heart's valves competent. The cardiac cavities contain dark fluid blood and partially decolourised clots. There is considerable atheroma of the aorta and coronary arteries, these vessels being also markedly dilated. The mitral valves are thickened at their base. Right lung adherent posteriorly and to the diaphragm; its posterior part congested and very œdematous; weight 21¾ oz. Left lung adherent posteriorly; congested and œdematous like the right; weight 19½ oz. — Abdomen: Liver soft and somewhat fatty; weight 40 oz. Spleen pulpy; weight 4 oz. Capsule of right kidney firmly adherent in many places; cortical substance pale and atrophied, and contains several small cysts; weight 3¾ oz. Left kidney in a similar condition; weight 4¼ oz.



Remarks.—As already stated, the chief interest in this case lies in the unusual position of the tumour. In recording a single case it is not necessary to consult the whole literature of a subject; I shall therefore be content to refer to Mr. Erichsen's excellent summary on intracranial aneurism contained in his "Science and Art of Surgery," pp. 81–87. From Sir Wm. Gull's sixty-two cases, it would appear that the basilar artery was affected in twenty cases, and the middle cerebral in fifteen; in eight of the remaining, the internal carotid was affected as it lay by the sella turcica, and in six others the aneurism was situate on the anterior cerebral artery. Although the causes of cerebral aneurism are stated by Mr. Erichsen to be obscure, in the present case there can be no doubt that it was due to the atheroma of the vessel. In it, as in those already described, the walls of the aneurism consisted of both coats of the vessel. From its position and size, and consequent pressure on surrounding nerve-tissue, no results followed; and during life no symptom existed to indicate its existence. There may have been optic neuritis, but no ophthalmoscopic examination was made.

For some of the preceding notes I am indebted to my colleague Mr. Davies.

ON

THE PHYSICAL CAUSE OF PRESYSTOLIC MURMURS.

By ALFRED H. CARTER, M.D. LOND.,
RESIDENT MEDICAL OFFICER TO THE GENERAL HOSPITAL, BIRMINGHAM.

THE subject of this paper was suggested by an article from the pen of Dr. Alexander Harvey, of Aberdeen, appearing in the columns of THE LANCET (June 12th and 19th); from which I gather that he not only finds insuperable difficulties in the way of accepting the explanation of Dr. Gairdner as to the physical cause of the so-called presystolic murmur, but that he doubts altogether its existence as an established fact.

The question he has raised is, I think, an important one, and one that should by this time be practically settled. Nobody doubts that the mitral orifice may be so contracted or altered by disease as to become an obstacle to the flow of blood through it. The question is whether such obstruction can and does give rise to an audible murmur; and if so, as to what are the characteristics by which it may be clinically recognised. I own that I am one of those who have been accustomed to regard a presystolic murmur as a frequent if not invariable result of mitral stenosis, admitting of as accurate a diagnosis as any other form of cardiac valvular disease.

In the first place, what is the meaning to be attached to the word *presystolic* as applied to a murmur? I understand it to imply a murmur which runs up to and ends with the first sound, which is the clinical expression of the commencement of the ventricular systole; and hence a murmur whose essential characteristic is that of immediate precedence of that systole. A murmur of this sort is, of course, in one sense diastolic, in that it occurs during the diastolic period; but the above term is preferable, as conveying additional and more exact information as to the characters presented by it.

In the second place, has such a murmur as here described, considered for the present altogether apart from the mechanism of its production, any existence in fact to the ear of an observer? This question demands a categorical answer either in the affirmative or negative. If the latter, then there is an end of the matter, as it is an obvious waste of energy to attempt to prove that mitral stenosis may be recognised by what cannot be shown to exist. But, on the other hand, once admit that such a murmur is not only heard but heard frequently, it behoves us to inquire into the conditions which are necessary for its production; and, since it is a morbid sign, to endeavour to correctly interpret its anatomical signification.

To repeat, then, I have heard over and over again—and my observations have confirmed those of many of the most accurate clinical observers—a murmur occurring during the diastolic (ventricular) period running up with increasing intensity to, and ending with, the first sound when this is present; or when, as is often the case, the latter is masked by a murmur, passing without interruption into the systolic bruit. There is frequently also an appreciable interval between it and the preceding second sound, which, indicating as it does the commencement of the ventricular diastole, shows that the murmur in question, in such cases, does not occupy the *whole* of the diastolic period. When this interval can be made out, which is not always, it follows also that it cannot be due to incompetence of the aortic valves, the closure of which is directly or indirectly the cause of the second sound, for murmurs from this cause invariably commence simultaneously with the second sound, or so much of it as may remain audible. But more of this anon. This murmur, as I have heard it, is of maximum intensity at the left apex, as determined by the site of impulse, though sometimes a little to the upper and sternal side of this spot. And, lastly, a large proportion, larger probably than that of any other cardiac murmur, is accompanied with a distinct and obvious thrill.

Admitting, then, this statement as an established fact, as, personally, I feel bound to do, I will pass on to investigate its most probable cause in the light of modern clinical knowledge. It will facilitate matters, I think, if we first call to mind what is going on in the normal heart at the time when this murmur is asserted to occur. Without going into all the details of the mechanism of the production of the first and second sounds, no one, I take it, is prepared to deny that they are respectively the direct or indirect result of the closure of the auriculo-ventricular valves on the one hand, and of the aortic and pulmono-arterial valves on the other. The former marks the commencement of the ventricular systole, both ventricles contracting simultaneously, and continues for two-fifths of a second, when, without any appreciable interval, it is followed by the second sound, the first result of ventricular relaxation, or, in other words, the commencement of the diastole. Then a pause for two-fifths of a second, during which blood flows from the auricles into the ventricles, which are already beginning to dilate: whether actively or passively does not materially affect my present purpose; suffice it to say that, relatively to the other cardiac movements, it is progressive, even, and gradual. During the whole of this time blood is also flowing freely into the auricles from their corresponding veins. At the end of this "physiological pause" the auricles are full, and the ventricles also, *so far as they have hitherto expanded;* but though the latter are full in this sense, they are not yet sufficiently distended for the purposes of normal circulation. But now another period of activity sets in: the auricle contracts, and, in contracting, forces the blood into the ventricle to its maximum physiological distension, and, this once reached, the ventricular systole immediately follows.

This auricular contraction appears to be Dr. Harvey's chief difficulty, if I mistake not. He objects to any such term as "forcible opening" of the cavity, and attempts to depreciate its importance by regarding the auricle as "essentially extraneous to the heart,—as being a mere appendage to it." But, quibble as we may about the precision of these terms, it simply comes to this: "forcible" means nothing beyond the exertion of force, which, if the auricle contract at all, must be the case. And, further, it is a perfectly gratuitous assumption that, because the amount of force exerted is relatively inferior to that of the corresponding ventricle, "it is an insignificant affair"; it should be remembered that the obstruction to be overcome is relatively a slight one, and no great amount of force is necessary for this purpose; the force, however, is in exact proportion to the obstruction.

Then again as to the "emptying." It seems irrelevant to discuss whether the emptying is absolute and complete, or only partial. At any rate, judging from the auricular contraction as it may be witnessed during life, there is good reason for believing that a considerable portion of its contents are discharged in the process, if it is not so completely emptied as the neighbouring ventricle. The auricular contraction, insignificant though it may be in one sense, is none the less real on that account: it is an established fact; it can be watched in action; and its duration has been accurately timed, and found to occupy one-fifth of a second (Marey).

The effect of this contraction is to complete the distension of the ventricles, and is immediately followed by contraction of the latter, with closure of the auriculo-ventricular valves.

Now what may be termed the "clinical pause" includes the physiological pause and the auricular contraction, inasmuch as the latter gives rise to no perceptible sound; it commences immediately after the second sound, and ends with the succeeding first sound. This pause is generally referred to clinically as "the diastolic period," and is essentially characterised by the passage of blood from the auricles to the ventricles. It is during this period, and especially towards the end of it, that the presystolic murmur is stated to occur. It is now so well known that constriction of a cardiac orifice may give rise to an audible bruit that it is unnecessary for me to do more than allude to the fact here. If, then, a murmur is heard at all during the diastolic period, there is no room for any other supposition but that it results either from obstruction to the flow of blood into the ventricle, or from the regurgitation of blood into it through the aortic orifice. The sole difficulty that remains is the diagnosis between these two varieties of murmurs, and that it is but slight in the vast majority of cases I will endeavour to show further on.

Next, let us look at the matter for a moment from another point of view, by assuming that the presystolic murmur, as above defined, not only exists, but also that it is the outcome of mitral obstruction (tricuspid obstruction being so extremely rare), and then test our position by physiological and anatomical fact.

The physical conditions which are necessary to the production of obstructive cardiac murmurs in general, as I take it, are these: the more or less forcible propulsion of blood from one cavity to another through a contracted communicating orifice. Any of these factors being absent, no murmur will result. With regard to the first point, "forcible propulsion," there is always ample pathological proof in the autopsies of those who have suffered during life from well-marked mitral stenosis.

In order fully to understand what we see under these circumstances, it is necessary to keep in mind the following points:—Whilst alluding to the physiology of a normal cardiac revolution, I drew attention to the two modes, so to speak, in which the ventricle receives its supply of blood; during the first and most protracted of which the auricle is in a condition of relaxation, and the blood is flowing onwards merely with the *vis a tergo* of the pulmonary circulation. The secondary effects of the additional strain offered by the contracted mitral orifice during each part of this process are most interesting. In the first part it is to cause dilatation of the auricle and of the cardiac terminations of the pulmonary veins; and in the second—that of auricular contraction,—to cause hypertrophy of the walls of this chamber; and lastly, during the whole of the diastole, the general result is that of increased tension of the pulmonary circulation, which is compensated for by hypertrophy of the right ventricle—an invariable incident, at one time or another, in the life history of all cases of well-marked mitral stenosis.

And what is the conclusion to be drawn from all this? Why, that a large quantity of blood is propelled with unusual force, and with increased celerity (owing to the diminution in size of the aperture of exit), from the left auricle into the ventricle of the same side through a contracted mitral orifice—circumstances more favourable than which could not be conceived for the production of such a murmur as the one in question.

Then, with regard to the fact of increased intensity of the murmur towards its termination. A most plausible explanation of this feature of a presystolic bruit follows as a matter of course, when we take into consideration the increase of force exerted by the auricular contraction over and above that exerted in the early part of the diastolic period.

And, once more, with regard to the interval before alluded to as frequently occurring between the second sound and the beginning of the mitral bruit, I would suggest as an explanation that, in these cases, during the early part of the diastole neither is the quantity of blood nor the force with which it is propelled sufficient to cause an audible murmur.

And now a few words in conclusion with regard to the clinical aspects of presystolic bruits. Every practical physician will admit that instances occur in which the greatest care and deliberation are necessary to ensure a correct diagnosis; in some, perhaps, it may be that a decided opinion is impossible; but, on the other hand, there are many in which the morbid condition is obvious, and is easily recognised; and, again, there are many of which, judging merely from the murmur as heard by the stethoscope, we are unable to speak positively, but become clearly apparent when the collateral circumstances and conditions are closely investigated. In the first place, a typical presystolic murmur, presenting all the characters to which I have previously alluded, uncomplicated by any other valvular disturbance, requires nothing beyond an intimate acquaintance with these features, and a sharp ear, to make a correct diagnosis a certainty. The only murmur that could possibly be mistaken for it is an aortic regurgitant; and if additional aid in coming to a conclusion is necessary, I think it may be found by attention to the following:—Aortic disease never causes accentuation of the second sound at the pulmonic cartilage (second left), and in my experience murmurs of this class are almost invariably heard more distinctly at the right than at the left side of the sternum at the level of the third rib cartilage. In mitral stenosis the reverse holds good in both instances. Again, the secondary effects on the heart and circulation are widely different in the two cases. In the former there is always some, and frequently very great, excentric hypertrophy of left ventricle, and the jerking pulse and throbbing carotids are almost constant accompaniments, whereas in the latter they are absent, and the right ventricle is hypertrophied.

Of course difficulties do occasionally occur, and the most serious of these arise from the frequent association with presystolic murmurs of others which, by reason either of their number, intensity, or duration, require the greatest care and the closest attention for their proper discrimination, sometimes even rendering this impossible. For instance, I can well imagine that a loud aortic regurgitant existing together with a presystolic murmur might render a differential diagnosis an impossibility; or, again, an association with a loud mitral systolic murmur of a similar pitch might also cause a great difficulty. But, as a matter of fact, there is frequently such a marked difference in pitch and quality between them as to render a diagnosis comparatively easy. There is a case at present in the hospital, under the care of Dr. Foster, which well exemplifies this.

Although much more might be said with regard to this matter, space only allows me to add that, if something yet is wanting to convince those who, with Dr. Harvey, still doubt not only the possibility of recognising presystolic murmurs, but also their very existence, I think it may be found on a careful perusal of the chapters relating to this topic in the recently-published "Essays on Clinical Medicine," by Dr. B. Foster, of this hospital, containing some of the practical experience of one who has worked much with a view of clearing up our knowledge of cardiac disease in general, and to whom personally I owe no small debt of gratitude for much of what ability I may possess to recognise and deal with difficult cardiac cases.

Birmingham.

CASE OF LONG-STANDING FISTULA IN ANO TREATED BY THE ELASTIC LIGATURE.

BY J. C. OGILVIE WILL, M.D.,
ASSISTANT-SURGEON TO THE ABERDEEN ROYAL INFIRMARY.

AMONG other purposes for which an elastic ligature may be employed, Professor Dittell mentions that of division of the tissues for the cure of fistula in ano; and though I do not consider that, as a rule, its use should be preferred to the cutting operation, in certain exceptional cases I think it may prove of advantage, of which the following is a well-marked example. The history of this case is reduced from a written statement supplied by the patient, and it certainly appears a very extraordinary one.

W. P——, aged fifty-one, states that in the summer of 1854 he suffered from great weakness of his back and legs, and severe pain after being at stool. He was then treated for "spinal disease" by the actual cautery, blisters, and the application of leeches round the anus. After being subjected to this treatment for eight months he attempted to resume his duties; but the pain after defecation continued, and even at other times he suffered so much uneasiness that, frequently after returning home at night, he applied leeches and poultices to relieve it. He continued in much the same state till August, 1864, when matter was observed issuing from an opening by the side of the anus. This discharge went on for eighteen months, during which period he had no pain at stool, but a feeling of great weakness and pain in the small of his back. During the next four years "red swellings" appeared from time to time round the anus, but with the aid of leeches and poultices they were got rid of. From 1870 to 1874 there was an occasional discharge of pus from a sinus, the flow sometimes continuing for three months, then stopping, and then again commencing; at times he could neither sit nor lie, but was obliged to walk about, which he found afforded greater relief than anything. In September, 1874, the pain while sitting increased, especially at one point on the inner side of the left buttock, where he could feel "something about the size of a pea, from which a hard cord extended to the anus." This swelling gradually increased, as did the pain; and he had again recourse to leeches and poultices, but, finding them of no avail, he applied to a medical man, who soon after requested me to see him.

On examination, I found a small opening in the perineum on the left side of, and distant two inches from, the verge of the anus. On introducing a probe, it revealed an indurated, deeply seated sinus, ending some little distance above the sphincter; but no internal opening could be detected. The lower part of the gut was separated from its surrounding structures to such an extent that the point of the probe could be swept round fully half its diameter.

Some days afterwards I completed the fistula by making an internal opening in the gut above the sphincter, and passed in a probe armed with a solid elastic ligature (similar to that described by Sir Henry Thompson in THE LANCET of Jan. 3rd, 1874), which I then, after detaching it from the probe, put tightly on the stretch and knotted securely. The ligature was considerably larger than the eye of a probe would admit, so I fastened them together by means of a thread of iron wire. At the moment when the ligature was being tied, the patient complained of considerable pain; but this soon passed off, and by the use of morphia suppositories he was kept quiet and comfortable. A pad of lint coated with an ointment containing salicylic acid was applied, and retained by a T bandage.

The ligature came away on the eighth day of the operation, and left a broad but healthy granulating surface, which gradually healed. The bowels were moved some days before the separation of the ligature, but its presence did not occasion any inconvenience.

In this case, on account of the length and depth of the fistula, considerable hæmorrhage would, in all probability, have followed the use of the knife; moreover the patient was weak from long suffering, of extremely sensitive and nervous temperament, the subject of heart disease, and much averse to a cutting operation; therefore I think it was a peculiarly suitable case for the employment of the elastic ligature, as not one drop of blood was lost during the entire proceeding, and the shock of the operation was much less than it would have been had division by a cutting instrument been the mode adopted.

Aberdeen.

THE FOOT-AND-MOUTH DISEASE.—This disease has broken out in Herefordshire among cattle and sheep, and has spread most disastrously among the famous Hereford herds. The last weekly returns show a favourable decrease on those of the previous week. In the Hereford district, according to previous returns, there were 585 head of cattle ill, while the last return shows 479 only. Unhappily, however, to counterbalance this, there is a large increase of the disease among the sheep, which number 613, and pigs 43.

UNIVERSITY COLLEGE HOSPITAL.

CASE OF DEPRESSED FRACTURE OF SKULL; TREPHINING; FUNGUS CEREBRI; DEATH.

(Under the care of Mr. John Marshall.)

For the notes of the following case we are indebted to Mr. A. Pearce Gould, late house-surgeon.

H. B——, a healthy young man, aged twenty-four, was admitted on Feb. 23rd, 1875, at 5 p.m., with the history that, while running fast, he had fallen and struck his head against a low spiked railing. He was on admission semiconscious, answering questions when spoken to loudly, but speaking petulantly. There was a wound in the scalp above and in front of the left parietal eminence; the finger introduced into this came upon a depressed fracture of the bone, and a small quantity of brain-matter was found protruding from the wound. The pupils were equal, of normal size, and acted readily to light; pulse regular, small, 96.

Mr. Marshall saw him at once, and ordered chloroform to be administered, under the influence of which the patient vomited. The wound in the scalp was lengthened at each end, and then another cut, four inches long, was made at right angles to it across its middle. The four triangular flaps of scalp were then reflected back, and the pericranium extensively raised from the fractured bone. The depression was formed by the driving in of three triangular plates of bone, having their apices firmly wedged together in the centre and their bases rounded. The depressed area was about one inch and a half in diameter. As the bone could not be elevated, a small trephine was applied at the anterior part of the exposed bone, and when the part-circle of bone was removed the depressed fragments were readily elevated and removed. A small spiculum of bone was then found to be sticking up vertically with its point in the dura mater, which had a rent in it at least an inch long. Loose pieces of the inner table of the skull were removed, and sharp corners taken off with bone-pliers. The brain was seen pulsating through the wound in the meninges, and arterial blood oozed up at each pulsation. The wound was syringed with very weak cold carbolic lotion, and lint soaked in this lotion was laid on it, and covered over with lint steeped in carbolised oil. The head was shaved, and the patient was put back to bed. When the bone was being removed the pulse increased in force and diminished in frequency.—6.30 p.m.: Is lying quietly in bed; answers questions quite rationally, but slowly. Pupils contracted, especially the right; pulse 100, full and bounding; respiration 20; temperature 100°. After about every ten respirations he makes a long pause, followed by a few very deep respirations. Ordered ice-bag to head and evaporating lotion to forehead. To take nothing but iced milk.

Feb. 24th.—Slept well through the night. Quite sensible this morning. Complains of frontal headache and pain round the wound, with severe paroxysms; forehead feels hot; skin hot and moist; pulse full, rather hard; tongue a little furred at edges, dry in centre; pupils equal, normal; has passed water voluntarily; bowels have not been open; urine pale, clear, acid, sp. gr. 1024, no sugar nor albumen. Dressings removed this morning; the wound syringed and dressed as at first. Temperature (axilla) 101°; pulse 104; respiration 20.—10 p.m.: Temperature 105·2°; pulse 105; respiration 21. Moaning, restless, half asleep; pain in the head almost the same as this morning; slight intolerance of light; pupils normal; pulse full, bounding, and rather hard; face pale. At 7 p.m. this evening he began to take one grain of calomel every four hours, and one drop of tincture of aconite every half hour.

25th.—Is in much the same state as yesterday. Mind clear; frontal headache; pupils equal, not contracted; no marked photophobia; no paralysis; no vomiting; skin dry, rather hot. Pulse 108, soft, jerky. Bowels have acted freely; wound dressed as before. The membranes are of a darker purple colour than before, and there is a slight protrusion of whitish brain-matter through the laceration in them; the edges of the wound are quite quiet; discharge slight and serous. Temperature 103·4°.—10 p.m.: Temperature 105°; pulse 130, rather irregular, soft; respiration sighing. Tongue dry; thirsty; bowels open again; no change in head symptoms.

26th.—2 a.m.: Pulse 108, very small, regular. To take the aconite every two hours.—11 a.m.: Had a short, slight rigor at 7.30, and another a few minutes since. Pain in the head has increased; felt sick this morning; pulse small, rapid; skin dry; tongue dry; bowels acted twice in the night; quite conscious. When the dressings were removed to-day there was a strong peculiar smell, resembling that of anatomical preparations. The hernia cerebri has more than doubled in size since yesterday; is now as large as a walnut, of white colour speckled with red, evidently consisting of brain-matter. The edges of the wound are granulating, and at one part adherent to the brain. Temperature 105·4°.—2 p.m.: Is less conscious. Has been twice sick. Pulse 128, regular and hard. To take aconite every half-hour. Respiration 40. The cerebral hernia is rapidly increasing in size, its surface now being as large as the external wound, pulsating in the middle, redder in colour, very soft and loose. A piece of lint dipped in carbolised oil is laid over it.—3.10 a.m.: Quite unconscious; eyes fixed; pupils equal, normal size; has been sick again twice. Pulse soft, small, irregular; respiration 56, very embarrassed; temperature 107·6° in rectum; 105·1° in axilla. The cerebral hernia is much larger, hanging over the lower edge of the wound as low as the left ear, very loose, with numerous dark-red spots, slight pulsation perceptible at one point, at the upper part; its surface is as large as the palm of the hand. The hernia increased in size until death, which took place at 4.50 p.m. Temperature in rectum at 5.10 p.m., 107·6°; at 5.30, 107·2°; at 5.50, 107·2°.

Autopsy, twenty-one hours after death.—Weather cold. Rigor mortis very great. The hernia cerebri has shrunk to about half the size it was during life, measuring two inches and a half by two inches, and appearing as a reddish-yellow mass. Dura mater very adherent to skull, presenting no abnormal appearance inside or out. A thin ridge of purulent lymph surrounded the part exposed in the wound, and effectually prevented the passage of fluid between the dura mater and the bone. The lateral ventricles contained rather less than their normal amount of fluid. There was purulent lymph in the arachnoid cavity over the upper and anterior part of the left hemisphere, but here only; no excess of fluid in arachnoid cavity. The vessels of the pia mater were injected all over the brain, and along the larger ones was an effusion of opaque fluid, and, at some points, of lymph; this condition was found over cerebellum and base of brain as well as on the hemispheres. There were patches of bright redness at some places, in which the vessels could be distinctly traced. The brain was notably paler than normal. On opening the chest, six ounces of dirty brownish-green fluid was found in the left pleura. On raising the left lung, the ligamentum latum pulmonis was found to have disappeared, and the lower lobe of the lung was extensively eaten away close to the spine; there was a rent in the œsophagus at the same place; the pleura was stripped off from the seventh and eighth ribs for some distance; no bruising around. These were supposed to be the effects of post-mortem digestion. Stomach healthy. Heart large, soft. Spleen large, dark. Kidneys congested. A little purulent lymph was found over the muscles covering the thyroid cartilage, for which there was no apparent cause. No other injury was detected.

MIDDLESEX HOSPITAL.

SPONTANEOUS CURE OF AN ANEURISM OF THE ABDOMINAL AORTA; DEATH BY URÆMIA.

(Under the care of Dr. Robert Liveing.)

The following case, for the notes of which we are indebted to Mr. Tomes, house-physician, presents many points of extreme interest. Although the aneurism, as shown by examination after death, was of considerable size, an important sign of aneurism—lateral expansion—was absent. At the post-mortem examination it was demonstrated that in this case, at least, the channel of circulation was behind the mass of the tumour. The supervention of albuminuria, and finally of uræmia, are facts of great clinical importance.

Elizabeth T——, aged fifty-two, was admitted into the Northumberland ward on April 27th. There was nothing of importance in her family history. She had borne ten children, three of whom were born dead; one miscarriage. She said she contracted syphilis from her husband sixteen or seventeen years ago; the miscarriage and two of the still-births were subsequent to this. The present illness commenced twelve months ago as an aching pain in the left side, worse at some times than at others. Subsequently it became continuous, and soon she perceived a small lump the size of a walnut midway between the navel and the breast-bone. The pain went on increasing, and the tumour grew, but very slowly. Of late she had lost her appetite, had retched frequently, and had also lost flesh.

On admission she was emaciated, and bore the marks of old syphilitic sores on the face, arms, and legs. Tongue furred and white. She complained of constant nausea; retched frequently. No appetite; and had a "burning" pain in the site of the tumour, not increased by food. There was great tenderness of the abdomen, especially about the right iliac region; percussion could not be borne. An irregular, roundish, hard lump, not particularly tender on manipulation, occupied the epigastric region, and extended into the left hypochondrium, about the size of a large fig; the upper border being half an inch below the xiphoid cartilage, its lower, which was less distinct, being about an inch and a half above the umbilicus; its right border extended a trifle beyond the median line of the abdomen, and was distinctly defined as a hard ridge, separated from the remainder of the mass by a sort of sulcus. Towards the left it gradually faded off under the costal cartilages. It was firm to the touch; dull on percussion; pulsated visibly and forcibly with the abdominal aorta in an antero-posterior direction, but had no lateral expansion. A bruit was audible on auscultation, synchronous with the pulse. The liver dulness was about normal. No ascites; no œdema of the lower extremities. The urine, when first examined, contained no albumen, sp. gr. 1015, pale. Some tortuous and dilated superficial veins could be felt under the skin of the abdomen. The nausea and retching continued in spite of bismuth and hydrocyanic acid. The urine was examined daily, and contained no albumen until the 8th of May, eleven days after admission, when she was suddenly seized with a marked epileptiform fit. After this had passed off the urine was drawn off, and found to contain a decided trace of albumen and granular casts. She was consequently wet-cupped over the loins, and given a large dose of compound jalap powder in a black draught; but the latter having no effect, croton oil was given. The fits recurred, however, with increasing rapidity, the patient being comatose in the intervals until death, which took place on May 12th. In all she had from twenty to thirty fits.

At the post-mortem examination, on removing the viscera was seen a large globular tumour the size of a common orange, springing from the abdominal aorta just above the origin of the renal arteries. The pancreas was wrapped over its surface; several large veins, of which the left renal was the most remarkable, being distended to the size of a forefinger, passed over its surface. On closer examination, it was found that the cœliac axis took origin from its upper part, that the superior mesenteric artery arose from its front, and the two renal arteries came from underneath its lower margin. The tumour felt highly elastic, and gave the impression of containing fluid. On slitting up the abdominal aorta from behind, it was seen that the tumour was a globular cavity communicating by a large open window with the aorta. It was completely filled with a fibrinous clot. On cutting open the clot it was found to be everywhere soft and elastic, and to present a greyish woolly appearance throughout, but no trace of concentric lamination. The arteries arising in connexion with the tumour were all of fair size and average calibre, but fluid injected with considerable force into the superior mesenteric failed to reach the aorta; there appeared to have been a free channel for the blood through the aorta itself, behind the tumour. The lower part of the thoracic and upper part of the abdominal aorta presented numerous white raised patches of atheroma. The kidneys were both intensely engorged with dark blood. The capsule was torn off with difficulty, leaving a rough granular surface. On section, no diminution of cortex. Consistence of kidneys tough. The left renal vein was bound down to the anterior surface of the tumour. A few patches of lobular pneumonia in the lungs. The other organs were healthy.

The cause of death in this case was evidently uræmia from renal disease, which must have arisen quite independently of any mechanical interference with the supply, or return of blood from the kidneys due to the aneurism; for, on the one hand, both renal arteries were of fair calibre and pervious, although arising almost from the sac itself. The left renal vein, it is true, took its course directly over the tumour, but, on the other hand, both organs were equally congested and granular. The case is especially interesting, since it shows that the absence of "lateral expansion" in an abdominal tumour may occur in connexion with an aneurismal sac filled with an organised clot.

HUNTINGDON COUNTY HOSPITAL.

EPITHELIOMA OF THE ARM, DEVELOPED ON THE CICATRIX OF A BURN; AMPUTATION; MISHAP WITH ESMARCH'S BANDAGE.

(Under the care of Mr. HOLDERNESS.)

FOR the notes of this case we are indebted to Mr. Greenway, the house-surgeon.

Abel B——, aged forty-nine, a brewer's man, was admitted on April 17th, 1875. When three years of age he was severely burnt on the right side and right arm by his clothes taking fire. The burn soon healed, except at a small spot over the elbow. This spot constantly kept healing up and breaking out again. Twelve months ago it broke out and rapidly spread all over the cicatrix until the arm presented a large ulcerated surface extending from about four inches below the shoulder to within two inches of the wrist-joint, encircling the entire limb. At the bend of the elbow was a large fungous mass, very tender to the touch, easily breaking down and bleeding, and discharging, together with the surface of the ulcer, very fetid pus. This fluid exhibited under the microscope, besides pus- and blood-corpuscles, a number of irregular-shaped, large, flat, thin scales, with nuclei and nucleoli, in some cases single and in others more than one. No history of cancer or syphilis could be obtained.

No disinfecting fluid had any effect in subduing the offensive fetor of the discharge until the whole surface of the ulcer was covered with a paste of chloride of zinc and opium. By this means all smell was quickly removed in a few hours. No improvement, however, occurred in the character of the ulcer, and, as it was evidently extending, amputation of the limb below the shoulder was proposed and performed by Mr. Holderness. At the operation, Esmarch's bandage was employed, and the elastic tubing was placed as high up the limb as was convenient, leaving space enough (as it was thought) for the circular incision to be made free of the margin of the cicatricial tissue. This, however, was not the case; for, immediately the incision through the biceps had been made, this muscle retracted beneath the tubing, and severe hæmorrhage from the unrestrained divided brachial and other arteries ensued. The removal of the limb was proceeded with, and the vessels secured with silk ligatures; not, however, before a good deal of blood had been lost. The stump has since progressed favourably, and is now almost healed. The point for consideration in connexion with this case is, What would have been the result of the early excision of the diseased spot at the elbow?—its character being recognised by microscopical examination of the discharge; and a lesson is taught that care is to be observed, in employing Esmarch's bandage, to leave sufficient space below the elastic tubing and the line of incision to prevent retraction of the divided muscles beneath it.

Reviews and Notices of Books.

Manual of Pathological Anatomy. By C. HANDFIELD JONES, M.B. Cantab., F.R.S., F.R.C.P., and E. H. SIEVEKING, M.D., F.R.C.P. Second Edition, revised, enlarged, and edited by JOSEPH FRANK PAYNE, M.B. Oxon., F.R.C.P. London: Churchill. 1875.

Lectures on Pathological Anatomy. By SAMUEL WILKS, M.D., F.R.S., and WALTER MOXON, M.D., F.R.C.P. Second Edition. London: Churchill. 1875.

STUDENTS of pathology—and who is there among practitioners of medicine that does not come within the designation?—may be congratulated on the simultaneous appearance of new editions of our two standard works on the science. Both have been for long out of print, and were indeed left far behind by the rapid progress of pathological work which the last fifteen years have witnessed. But their places remained unfilled in English medical literature, and we welcome their reappearance. The work of revision could not have fallen into better hands. The contributions to pathological knowledge which have been made by Dr. Moxon and Dr. Payne are many and various, and not least must be reckoned the excellent way in which each has performed his task in editing our handbooks of the science.

The general characteristics of the manual of Jones and Sieveking are well known. Its aim is to give an account, as full and comprehensive as is compatible with brevity, of what is known and conjectured regarding both general pathological processes and special organic changes. A useful description is given of each, and both facts and opinions are presented with clearness and impartiality, and the work is, on the whole, well brought down to the present day. The more important classical treatises have been freely used, the repertorium of pathological knowledge contained in the Transactions of the Pathological Society having been laid under free contribution.

The pathology of the general morbid processes, with an account of which the work commences, has furnished the editor with some of his most important work. The modern observations on the pathology of inflammation are incorporated with the old material. The great controversy on the part played respectively by tissue-cells and blood-corpuscles in the phenomena of inflammation and suppuration is only briefly alluded to for want of space, but the general conclusions are given. The editor avows himself convinced of the participation of the tissue-elements in the process, as well as the bloodvessels and cells. Septicæmia and pyæmia also occupy considerable space. The outline of the chief experimental evidence on the subject, which has of late been so abundantly furnished, is too brief to do anything like justice to recent investigation; but, so far as it goes, it is clear and fair.

In the revision of the section on Tumours, Virchow's work on Morbid Growths has formed the basis of the alterations and additions. The section has, indeed, been almost rewritten. The classification adopted is that of Virchow. Some forms of tumour are rather too briefly described, but the general questions incidental to the description of cancer and tubercle are very well discussed.

The special pathological anatomy of the various organs makes up the largest part of the volume, but into the details of this part it is impossible for us to go. The work of revision is here also on the whole well performed. The field is scanned with great completeness, no subject of importance being omitted. Here and there further additions might have been made with advantage. The account of the changes in the brain which are consequent on embolism needed fuller elucidation, and the pathological anatomy of the spinal cord is scanty. In the original edition it was very defective, and the trifling additions made fail altogether to bring it up to our present state of knowledge. Morbid conditions of the heart's walls are also too briefly given—a subject on which very much has been done since the first edition appeared. The account of the histology of both hypertrophy and fatty degeneration is very imperfect. With these and other similar exceptions, of no grave moment, incidental to the wide field to be surveyed, the work is well done. Every addition is clear and to the point, and those subjects which are still under discussion are impartially considered—arguments most relied upon on each side being given, and the most probable conclusion educed, without too great detail of the conflicting evidence. The book is in all parts pleasantly free from any attempt at dogmatic decision on doubtful questions. The illustrations of the first edition are supplemented by many fresh woodcuts, some from Rindfleisch and other continental works, others from original preparations by the editor, and many of the latter are of great excellence.

Dr. Wilks's "Lectures on Pathological Anatomy" were published originally in 1859, and the work was soon out of print. The task of the preparation of a new edition has been long, the preface informs us, in the hands of Dr. Moxon. The work itself bears evidence of much labour in its reconstruction. It could hardly have fallen into better hands. The great feature of Dr. Wilks's work was its original character, and this feature has been well maintained by Dr. Moxon in his additions, which, in some parts, amount to rewriting. In many portions, indeed, merely the skeleton of the old work remains, and has been reclothed with new material, and it may be questioned to whom the larger share of the work, in its present aspect, is to be ascribed. The chapter on Diseases of the Lungs alone has been revised by Dr. Wilks.

The pathological anatomy of the various tissues and organs of the body constitutes the subject of the work. General pathological processes are discussed only incidentally where they have special relation to the changes in certain organs, and at the end of the volume some of the morbid conditions which have been described under the head of certain organs are grouped together in their associated connexion, as they are seen in certain special diseases.

The work represents essentially the pathological experience of its two authors. The rare advantages which they have possessed of extensive, almost unrivalled, opportunities for observation, and the ability each has shown to make the best use of those opportunities, have enabled them to describe and discuss almost the whole range of the subjects which pathological anatomy embraces, in the light of their own observations and of their own careful and well-informed reflection. This confers a unity and consistence on the whole work. There are no uncemented facts, no disjointed quotations, no unmarshaled statistics. All parts are compactly grouped and welded together. In the preface to the original edition we were told that its pages contained no statement unverified by the author's own observation and experience. This, while it unquestionably added, perhaps incalculably, to the value of the work, was impressed upon its form very distinctly. The statement is true, though not to an equal extent, of the present edition, but the effect upon its style is even exaggerated, and the first person is predominant throughout to an extent which is not always quite fair to other workers, especially in a treatise which professes to, and does, present to a wide circle the pathological knowledge of the present day. The work is, however, one of great value, and the additions which have been made to it, in the completeness of range, and the thorough practical knowledge which each displays, leave nothing to be desired, and bring it in every respect thoroughly up to the present day. Its style is clear and exact.

Of the several sections we can only briefly speak. Almost every chapter has been extensively altered, none more so than the first one, on Diseases of Bone; the question of inflammation of bone being discussed with much ability. Diseases of the Heart receive very full discussion, as also do the Diseases of the Arteries, to which Dr. Moxon is known to have paid much attention. "Arterio-capillary fibrosis" meets, it is to be remarked, with little favour. An excellent description is given of the pathological anatomy of the brain and cord; which, although brief, is by far the best that exists in an English work, the results of the most recent observations being incorporated in the description. The chapter on Diseases of the Lungs has been revised, as we said, by Dr. Wilks, and it contains an excellent account of the morbid changes which underlie phthisis, the several views of their pathological character being stated with great clearness and impartiality.

The account of the Morbid Anatomy of the Stomach embraces an interesting discussion of the pathology of gastric ulcer. The view is rejected as unsatisfactory which ascribes its origin to the action of the gastric juice on an area in which an accidental arrest of circulation has taken place. Indeed, Pavy's explanation of the absence of self-digestion—that the circulating alkaline fluid neutralises the effect of the blood—is regarded as insufficient. The authors are inclined to attribute the occurrence of the ulcers to nervous influence, and to associate them with simple ulcers of the cornea.

In the description of Changes in the Liver, the mode of origin of hepatic abscess is considered at length. The theory of the mechanical action of embola in causing secondary abscess, on which stress has been laid, is doubted, and they are ascribed to the irritating quality of the clot from the inflamed region setting up a similar morbid action in the liver tissue.

A very good account is given of the Morbid Anatomy of the Kidneys. The identity of most forms of acute Bright's disease is strongly insisted upon; the various states of kidney representing the several stages of the affection. The authors have themselves met with no facts to suggest that a contracted kidney may be the ultimate stage of an acute inflammation.

The final section contains, besides the description of the association of diseased states, some excellent suggestions on the points to observe in making a post-mortem examination.

THE
OUTBREAK OF ENTERIC FEVER AT MÜLLER'S ORPHANAGE, ASHLEY DOWN, BRISTOL.

WE regret to state that the outbreak at Mr. Müller's Orphan Asylum near Bristol has assumed serious proportions; no less than 500 children being affected, of whom twelve have died, whilst others remain in a precarious condition, but no fresh cases have occurred during the last few days.

The asylum consists of five large separate buildings, and nearly 2000 children are maintained in them. The management of this huge establishment rests entirely with Mr. Müller, there being no committee, nor are any of the usual means of raising funds employed, Mr. Müller relying entirely on the efficacy of prayer to replenish his exchequer when it falls low. The buildings are well constructed, well ventilated, and are connected with the Bristol system of sewage. The water-supply of the establishment is taken from wells situated on the premises; the water is good, and the city analyst, Mr. Stoddart, reports it free from organic impurities. The water has been again analysed since the outbreak, with the same result. From a visit we paid to the asylum some few years ago, we can bear witness to the excellence of the domestic management, and the happy and contented appearance of the children.

For the details of the present outbreak we are indebted to Dr. Davies, the medical officer of health for the city of Bristol, who has most kindly furnished us with an account of the outbreak, so far as he has been officially connected with it.

The first notice received by Dr. Davies of the occurrence of the outbreak was on the 26th of July, when the local registrar returned five deaths from fever and one from hæmorrhage, which, on subsequent inquiry, proved to have been a case of typhoid, as having occurred at the asylum. Dr. Davies at once visited the orphanage, and obtained the following information. The disease commenced on the 24th of June. At first nearly 30 sickened, and these cases were severe. The disease was entirely confined to houses 2 and 5. Dr. Davies suspected the water-supply obtained from the wells on the premises, but failed to establish any proof of their having been contaminated. He then inquired about the milk-supply, but as the same milk was used in all the five houses, and only the inmates of 5 to 2 were attacked, that source of infection was eliminated. Dr. Davies, however, persevered in his inquiry, and presently learnt that the children were in the habit of playing in a picturesque dingle situated near the asylum, at the bottom of which runs a small stream of water fed by ditches containing the sewage of the several private houses on Ashley Down. Dr. Davies also learnt that fever has recently prevailed in these houses. The children, it appears, were in the habit of drinking the water when out for their afternoon rambles. Dr. Davies believes this to have been the original source of the mischief, and we quite agree with him, but we think that the subsequent extension of the disease in buildings Nos. 5 and 2, and the strict limitation of the fever to these houses points to some local defect in their sanitary arrangements; unless, of course, it can be shown that the inmates of these two houses alone had access to the contaminated water of the valley. What we think most likely to prove the case is that a certain number of children in house 2 and 5 received on a given day a dose of specifically contaminated water, and subsequently sickened with enteric fever. The disease thus introduced into the houses spread, owing to local sanitary defects in the buildings themselves, and as these defects were probably limited to these two buildings, the fever was not introduced into the other blocks.

The preventive measures that have been adopted by Dr. Davies are admirable, and will no doubt prove sufficient to check the extension of the disease in other quarters of the neighbourhood. With regard to the polluted streams that have caused the mischief, Dr. Davies, some months back, served notices on the owners of the houses on Ashley Down to abate the nuisance; but it was found that Ashley Down and its watershed lie above Bristol, in a separate sanitary district. The Bristol sewers are constructed only for the parliamentary borough of Bristol, and cannot take the sewage of outlying districts on a higher level, the result being that the sewage of the rapidly increasing suburban districts round Ashley Down is discharged into the open streams which pass through the town of Bristol to discharge itself into the harbour! To remedy this condition, Dr. Davies suggests that the sanitary authority of the district should be made coextensive with the watershed. It affords another instance of the absurdity of the present system of artificially dividing our sanitary authorities into urban and rural, when the interests of both are in so many cases identical.

In conclusion, we would comment on the extraordinary fact that, although enteric fever had been spreading rapidly in the orphanage for more than a month and 500 cases had sickened, no official intimation had been sent to the medical officer of health of the district, who did not learn of the outbreak till no less than five deaths had been reported by the registrar. This omission of a plain and obvious duty might have been followed by most disastrous consequences to the city of Bristol. We desire to express our sympathy with Mr. Müller during this trying time, and we sincerely hope that the public attention which has been drawn to this useful institution by the occurrence of the outbreak will secure for it increased support, and that Mr. Müller will be able to carry on his good work even more successfully than before.

THE LANCET.

LONDON: SATURDAY, AUGUST 7, 1875.

THE British Medical Association has this year held its meetings under exceptionally favourable circumstances. Although there was at first considerable objection raised by some of the Edinburgh authorities against holding the meeting in that city this year, and although there is still some resentment at the manner in which some of the leading members of the profession in Edinburgh have been treated by the Council of the Association, it must be confessed that at least the great majority of those who congregated in the Free Church Assembly Hall on Tuesday last were prepared to sink all personal considerations, and to contribute as far as possible to the success of the gathering. The traditions and the associations of the venerable city of Edinburgh and its illustrious University are calculated to inspire the most indifferent with a love of knowledge and a desire to increase his store, although the enthusiasm of most must have been damped when the President in his address pointed out the serious mistake they had made in not commencing and completing their educational career at the University with which he has so long and so honourably been identified.

The British Medical Association is certainly advancing in numbers, but, as one of the members suggested at the second general meeting, it may be doubted whether it is advancing in a corresponding ratio in influence and power. It was impossible to attend the general meetings and not to be struck with the want of control that the body of the members exercise over the management of the affairs of the Council. A great part of the business had been prepared in council, and offered cut and dried for acceptance at the general meetings of the Association, without any discussion, and even without any consideration. For instance, the report of the Council and the alterations in the bye-laws were accepted without being read by the few members who had not entirely subsided under the influence of the President's long address. It cannot surely be necessary to urge upon the members of the Association to insist on their right to supervise and superintend the working of the Council. The fullest confidence, it is true, must be reposed in the members of the Council; but if the great body of members are not allowed to discuss the official acts of their Council, or if they suffer themselves to accept and adopt whatever may be presented to them without previously ascertaining the nature of the proposition submitted to them, it is needless to say that they will soon lose their influence and independence, and that the Council alone will, in deed and in fact, become the political representatives of the British Medical Association, in which those members outside the Council have no voice or part, except the responsibility which attaches to them as members of the incorporated Association. The spirited protest offered by two or three of the more public-minded members of the Association will doubtless bear some fruit.

◆

SOME eight or nine years ago we took occasion to comment somewhat extensively and categorically on certain faulty items of administration at St. Bartholomew's Hospital, and to point out how, as it appeared to us, much of this arose from a sort of antagonism in little matters between the lay and the medical staff. *The Times* and other contemporaries followed our example in this important instance, and the evils then complained of are now remedied. It is nearly two years since the attention of our readers was called to the same kind of abuses as existing at the Seamen's Hospital, and it was shown indubitably that, in consequence of the undue predominance of the lay element in the administration, the institution was suffering both in usefulness and prestige. But in this case, also, certain reforms were organised and adopted, and the result has been eminently satisfactory, both as regards the patients and the officers. We thought, indeed, that this unwise and absurd antagonism between lay and medical authorities in our large hospitals had ceased to exist, and that the position of our own cloth was now duly and properly acknowledged. But it is not so as yet. The administration of the so-called Royal hospitals is still, for all practical purposes, entrusted entirely to one lay official, denominated the treasurer. He lives, or is supposed to live, in the building, and, though assisted theoretically by a number of so-called almoners, his reign is purely autocratic. A question has very lately arisen at St. Thomas's—one of these Royal hospitals—that shows the working of the system. The medical and surgical staff, with the exception of the two senior members, came to the unanimous conclusion that it was desirable to change the hours for visiting their respective wards. For some years it has been the custom with all to make an early morning round, which, for obvious reasons in connexion with consulting practice, is found to be very inconvenient. The treasurer and almoners were communicated with, and a desire was expressed by the staff that the recognised hours of visiting might be fixed in the afternoon. We do not care to record the minute particulars of the discussion, but it suffices to say that the treasurer, having remarked that the change would be inconvenient to the nursing staff and to others concerned, announced that no alteration could be made. In arriving at this decision, Sir FRANCIS HICKS was doubtless influenced by the want of unity in the medical camp, the two elders standing aloof and doing nothing. The nursing element, too, is very strong at St. Thomas's; for, besides the regular nursing staff, so ably commanded by Mrs. WARDROPER, there are the probationers of the Nightingale School, whose convenience had doubtless to be consulted. Be this as it may, we have here a glaring result of the antiquated system of hospital management. A large body of professional men, including in their ranks some of the most eminent physicians and surgeons in London, are compelled, or rather permit themselves to be compelled, to adopt a course of action injurious to themselves and (if we except the convenience of some few persons of very secondary importance) of no practical benefit to any concerned. If precedents are wanted for the afternoon visit, we have only to look at other hospitals. If we are told that eight o'clock in the morning is a specially convenient hour, we assert that at this hour neither patient, nurse, nor ward can be properly prepared for the doctor's visit. The washing, dressing, and breakfasts of the patients must be "scamped," particularly of course in the winter, to their great discomfort and detriment; and all who know anything about the necessary work to be done in a sick room or ward will agree that, before at all events half-past nine or ten o'clock, the physician or surgeon is an unwelcome visitor, emergencies excepted. And therefore, for these reasons alone, we believe that the staff, in the interests of their hospital clients, acted wisely in endeavouring to change the visiting hour. Without, however, canvassing their motives, it is enough just now to consider whether the highly skilled work continuously given by our profession in the wards of these large hospitals is to be wholly and entirely subordinated in fact to one lay official. There is work enough for that gentleman without such acts of supererogation and unnecessary annoyance. If we are rightly informed, the structural arrangements of the resident medical officers' quarters are neither palatial above nor by any means perfect below; and we may here in connexion therewith call attention to the fatal cases of typhoid recorded in THE LANCET of last week, no particulars as to which have yet appeared. The treasurer in these large institutions is appointed to look after the funds, to consult with the architect, surveyor, and engineer in order that the buildings and their surroundings may be properly kept up, to see that nothing is wanting to promote the comfort of the inmates, and to co-operate cordially with the medical staff. As we remarked some time ago in dealing with a kindred subject, no institution that depends for its very existence upon skilled professional work can be properly conducted unless the dignity and status of the professional workers are duly considered and supported. And so we recommend Sir FRANCIS HICKS to concentrate his great administrative powers upon finance, drains, bricks and mortar, and, following the worthy example of a fellow-treasurer in the City, to leave the doctors to do their own work in their own way.

◆

DISEASES like small-pox, typhus, and typhoid fevers are attended with such marked symptoms, and are so frequently followed by a fatal issue, that they could not fail to arrest the attention of the most inobservant and excite the fears of the most heedless; but the case is very different when we come to study the history of granular disease of the conjunctiva and contagious ophthalmia. And yet outbreaks of these affections in schools and pauper institutions are not by any means infrequent occurrences. Whether we regard its insidious nature or the great difficulty of eradicating ophthalmia when once fairly established in a community, or the disastrous results by which it is followed, as far as the integrity of the vision is concerned, this subject is much more important than is commonly imagined. And the study of it does not lack practical advantages, for ophthalmia is in a great measure a preventable disease, its causes being mainly such as are attributable to defective hygiene and bad management. It is only of late years, moreover, that the nature of the disease has been properly appreciated. Under the head of conjunctivitis very dissimilar affections had long been grouped together. The disease, which was the great scourge of our own and other armies, which gave rise in the aggregate to an enormous amount of ineffectiveness and invaliding from those services, and caused a large number of unfortunate soldiers to be cast like beggars upon society in a disabled condition, has now in a great degree been overcome by improvements in barrack hygiene at home and foreign stations, especially at the latter. Every ophthalmia does not end in granular lids, nor are all granular lids the results of one and the same disease. The affection to which we are alluding was observed and described by military surgeons long before its features were thoroughly recognised by civil practitioners. This was partly to be attributed to the greater frequency of the disease in the army in past years, and the consequently greater familiarity of military surgeons with it; partly to the fact that in its initial stages it was rarely seen at ophthalmic institutions to which the sufferers applied when its characteristic phenomena had been merged in, or overlaid by, inflammatory conditions or their results. Now, however, the ophthalmic affection known as granular disease of the conjunctiva has been investigated by numerous observers in this country and abroad; its varieties and stages have been recognised, and much light has been thrown upon the causes of its prevalence in schools and other large overcrowded institutions. It was found by Dr. FRANK and Dr. MARSTON that the pellucid-looking granules to which the expressive name of "sago-grain" or "spawnlike" granulations was given, were common among soldiers placed under abnormally depressed or insanitary conditions; and it has since been established that these bodies had their anatomical seat in certain physiological follicular structures developed out of the subepithelial adenoid tissue of the conjunctiva. The presence or absence of these hypertrophied follicular growths in the conjunctival tissue may be regarded, moreover, as affording a delicate test of the sanitary state of a community. Their presence in man or animals, speaking generally, is indicative of hygienic deficiencies, like phenomena being induced in both under like surroundings. The fostering conditions are vitiations of a hot and moist atmosphere, from impalpable excreta of breath, skin, and body, consequent on imperfect ventilation. Mr. BRUDENELL CARTER, and many other observers, have made us familiar with the affections grouped together as contagious ophthalmia; and Mr. EDWARD NETTLESHIP, in two admirable papers in the *British and Foreign Medico-Chirurgical Review* for October, 1874, and January, 1875, has very exhaustively and intelligently discussed their symptoms and causes. Mr. NETTLESHIP points out that precisely the same combinations of conjunctival diseases are common among the poorer classes of this and other countries as are found in schools for the children of such people and in the ranks of the army. He thinks that granular ophthalmia had existed for an indefinitely long time in many European countries before the date of the Egyptian campaign. The presence of "sago-grain," or indeed any other form of granulation, indicates a vulnerability of the conjunctiva on exposure to relatively slight exciting causes of ophthalmia, and where such a condition exists we may expect a chronic ailment, liable to frequent recurrences of superadded inflammation, but capable of being altogether overcome in time with care and vigilance. Authorities differ a good deal as to the influence of contagion as a cause of the spread of the disease. Mr. Nettleship, for example, appears to agree with Mr. Welch, the Assistant Professor of Pathology at Netley, who has written several excellent articles on the subject, in thinking that too much has been attributed by authors to contagion as a cause, and he dwells particularly on dampness of the atmosphere as a factor of the disease; but although it may be impossible to prevent a considerable number of the poorer classes from being affected with slight degrees of granular ophthalmia when occupying overcrowded dwellings in a damp climate, Mr. Nettleship considers that its extensive prevalence in a severe degree shows a culpable neglect of hygienic rules among the body of persons so affected. When ophthalmia exists in any institution we may fairly assume that deficient stamina and ill-health are associated conditions, requiring attention to proper dieting, and that a "thinning out" of the occupants, with more air, more out-door exercise, and a greater attention to ablution and personal cleanliness on their parts, are required. It might be worth while to make some experimental inquiries into the condition of the atmosphere of institutions where ophthalmia prevails, especially as to its alkalinity and the amount of organic matter and moisture in it. And it is a practical hint, worthy of being borne in mind, that dust is frequently an exciting cause of ophthalmia, for we remember a case in which the surgeon of a regiment had recourse to a water-cart for watering the barrack-yard and parade-ground with manifest advantage.

The Report of the Select Committee of the House of Commons on the subject of the Hampstead Hospital for Fever and Small-pox, to which we briefly drew attention last week, finally sets at rest this long-vexed question. It will be remembered that the scope of the inquiry of the Committee was strictly limited to one question—viz., the action of the Metropolitan Asylums Board in respect of the establishment of this hospital; and their report is therefore mainly confined to this question. It was not, in fact, the principal function of the Committee to inquire whether the existence of the hospital on its present site could be proved to have been prejudicial to the health of persons or the interests of property in the neighbourhood, nor by what means such evil effects might be counteracted or remedied, or whether they were of such a nature as to necessitate the removal of the hospital; and although a large amount of evidence was gone into on these questions, the Committee appear to have framed their report from the strictly legal view of their powers, and to have limited themselves to the question of whether the managers of the Asylums Board had acted within their right in placing and maintaining the hospital in its present situation. It need hardly be said that the *onus probandi* lay with the opponents of the hospital, and that from this point of view any proof of evil results incidentally arising, or due to the action of others, was of no value as showing that the Board had acted in opposition to, or in violation of, the powers conferred upon them. And taking this strictly legal view of the case, the Committee, or rather the majority of them, were obviously averse from fettering the Board in the exercise of powers which have in the main been used with discretion and for the public benefit. Had the question been discussed from a different point of view, it is possible that they might have come to a different conclusion.

It is, we think, to be regretted that the Select Committee do not discuss more fully in their report the evidence given with respect to the actual dangers which have arisen from the hospital, and that they have made no recommendations for the suppression of evils which they allow to have existed. It is satisfactory to observe that they report that "medical evidence on both sides abundantly shows that infectious hospitals are not of themselves necessarily a source of danger to the adjoining district; that the evils inseparable from their existence may, by good management and proper precautions, be reduced to a minimum." At the same time they allow "that some alarm was experienced and some risk encountered in the immediate neighbourhood of the asylum during the period of the small-pox epidemic; although they are of opinion that such mischiefs have been exaggerated, and that they are not of necessity incidental to the existence of the hospital, but are mainly due to the carlessness of persons entering or leaving the same, or to the imperfect control which follows overcrowding." But seeing that the existence of such evils was established, and that similar conditions will always exist, and must operate far more injuriously in this situation than in many others, it would have been more satisfactory if the Committee had suggested some means by which the dangers might be diminished. And so with regard to the ambulances, concerning which there is some very strong positive evidence of the spread of contagion, owing to the neglect of the most ordinary precautions, the Committee, whilst careful to state that the Asylums Board have no control over them, and that they may be so regulated as to be free from objection, fail entirely to suggest any regulations, or to state by whom the precautions are to be enforced. It will be seen that the medical evidence on both sides, and the conclusions of the Committee as to the real sources of danger, agree in the most striking manner with the conclusions of the inquiry of our Sanitary Commission, the report of which we published eight months ago.

With respect to the alternative site (No. 3), the Committee allow that it possesses some advantages, but they do not consider that these are sufficient to counterbalance its greater distance from the dense population of St. Pancras, and the fact of its situation on the extreme verge of the metropolitan district.

In concluding the report, the Committee state that it has been made clear that the Hampstead Hospital is not required for the purpose of a third permanent infectious hospital, and that all that is now contemplated is the completion of administrative offices in substantial materials. Had this been stated some time ago, much of the agitation would never have been aroused; but, as a matter of fact, the plans for the complete rebuilding of the hospital as soon as the Board could afford the outlay were long ago completed. But for some time, at any rate, it appears that the hospital will only be used as an overflow hospital when the others are full.

The sole recommendation of the Committee appears to have been introduced with the view of preventing all such agitation in the future: it is that a compulsory power of purchase should be conferred on the Asylums Board, with corresponding power of compensation. This would doubtless be a great advantage if accompanied by sufficient safeguards, and might get rid of the suspicion of jobbery which has been necessarily associated with a more or less secret purchase from persons connected with the Board.

We hope that the result of the inquiry of the Committee will be to calm some of the excitement on the subject, and that the enormous outlay involved by the agitation and the inquiry will have brought about some good result. The somewhat extravagant laudations bestowed upon the Asylums Board will, we fear, rather mar the effect of the report, and will tend to support the idea of the Hampstead people that the Committee was not very fairly selected; but we trust they will accept the humiliation of defeat with as good a grace as possible, and make the best of the inevitable.

It is satisfactory to observe that Lord Sandon, in replying to Mr. Cowper-Temple's question as to the course likely to be taken by the Government next session in regard to the admission of women to the medical profession, spoke with much reticence. "At this late period of the session they did not feel themselves to be in a position to consider this important subject; but they would give it their best attention, and next session they would be prepared to state whether, in their judgment, legislation was desirable or not." Nothing could be more cautious than this answer. Lord Sandon, in the course of his remarks, only did justice to the great care with which the Medical Council considered the subject which was referred to them by the Government. It was natural, perhaps, that Mr. Cowper-Temple should give a somewhat partial view of the report of the General Medical Council on the subject, or rather that he should make the most of those suggestions of the Council which were in accordance with his own views. The General Medical Council, he says, made a suggestion which seemed very practical. They proposed not to interfere in any way with the existing examination or existing studies, but that a new and special examination should be provided for female students who might wish to prove their competence for admission to the Register. It cannot be too clearly remembered in what conditional form this suggestion of the Council was made. The qualifications are a most important part of the report to the Government. The report of the Council took very much the following shape:—The Medical Council are of opinion that the study and practice of medicine and surgery, instead of affording a field of exertion well fitted for women, do, on the contrary, present special difficulties which cannot be safely disregarded; but the Council are not prepared to say that women ought to be excluded from the profession. If it should appear to the Government and the Legislature expedient that women, who desire to obtain a legal status as medical practitioners in this country, should not be debarred from obtaining that status, the Council are of opinion that it should be under certain arrangements. Then follow the arrangements suggested by the Council; one of which—that mentioned by Mr. Cowper-Temple—is to the effect that, in the interests of public order, the education and examinations of female students of medicine should be conducted entirely apart from those of male students.

It will be seen from this that Mr. Cowper Temple gave to the House an imperfect view of the representation of this subject made to the Government by the General Medical Council. Mr. Russell Gurney also fell into much the same error in saying that the Council had expressed a decided opinion that women ought no longer to be excluded. They simply said that they are not prepared, notwithstanding the special difficulties in the way of women following medicine as a profession, to say that they should be excluded. They throw the whole responsibility of admitting them on the Government, on whom it should properly be thrown. We entirely approve of the Council's way of putting the matter, and we should not disapprove of the Government cautiously, and under the arrangements suggested, removing the legal obstacles to the admission of women. But nothing is to be gained by "disregarding the special difficulties" of this question. As Lord Sandon says, it is an important subject. If sex is to be no hindrance to the pursuit of the medical profession, it can be none to any other. In other words, the legislation which would admit women to medicine will mark a new era in social and political history, the effects of which may be more felt in other professions than in ours. It is in this large view that the question must be considered by statesmen, and they may well take the interval between two consecutive sessions for the purpose of such consideration. We are not afraid of being met in our profession by large numbers of competitors in the form of girl-graduates. At any rate, we prefer to rely on the protection afforded by "special difficulties," rather than on that afforded by laws which have an ungracious look of exclusion.

Annotations.

"Ne quid nimis."

THE HEALTH OF ENGLISH WATERING-PLACES.

The information now published once a year by the Registrar-General relating to the health of our principal English seaside and inland watering-places affords an indication of their relative sanitary condition which, if not scientifically accurate, has a well-defined value. The districts and subdistricts taken by the Registrar-General to represent the forty-six watering-places, treated of in his table, contained a population estimated in the middle of this year at little less than a million persons. The annual death-rate in this population during the second quarter of this year was 18·4 per 1000, against 18 in the same period of last year. This increase was less than the average increase which occurred throughout the country, due to the exceptional fatality from diseases of the respiratory organs. The death-rate from the principal zymotic diseases in these forty-six watering-places, which was equal to 2·2 per 1000 in the spring quarter of 1874, declined to 1·3 in the three months ending June last; this may be accepted as evidence of improved sanitary condition. The zymotic rate did not exceed 0·5 per 1000 in Bognor, Worthing, Sidmouth, Harrogate, Dover, Southend, Cheltenham, and Buxton; while it exceeded 3 per 1000 in Folkestone, Whitby, and Eastbourne. During the quarter ending June 30th last the fatal prevalence of whooping-cough caused an excessive zymotic rate in Eastbourne, Whitby, and Southport; while the high rate in Folkestone and Aberystwith was due to measles. It is open to discussion how far the comparative sanitary condition of watering-places may be judged from their general death-rates; the value, however, of information as to the relative fatality of zymotic disease in different communities for such a purpose can hardly be doubted.

THE CHEMISTRY OF THE BLOOD.

In a recent communication to the Académie des Sciences, M. Gauthier describes a series of experiments on the influence of salt on the coagulation of the blood, an extension of the observations of Hewson, Davy, Dumas, &c. He found that the known effect in retarding coagulation was produced equally by chloride of potassium and by chloride of sodium, and that the maximum influence was obtained, in the case of the blood of the bullock, sheep, dog, and rabbit, when the proportion of the salt was 5 or 6 per cent. The retardation amounted to nearly twenty-four hours. A larger proportion had less effect. The corpuscles preserved their form, and even exhibited slight contraction, and, by simple filtration, could be separated from the plasma. The plasma could be preserved almost indefinitely as a clear liquid, coloured a slight rose tint. On the addition of water, which of course lessened the percentage of salt, it formed a firm and transparent coagulum. The plasma he found could be dried in a vacuum, and reduced to a greyish powder, which would redissolve in the same quantity of water, the resulting solution speedily coagulating on the addition of more water. The dried plasma did not lose its property by exposure for an hour to a temperature of 110° C.; its solution in water coagulated on dilution just as did the undried plasma. The coagulability of bullock's blood was unaffected, he found, by hydrocyanic acid, cyanide of potassium, arsenite of soda, strychnine, curara, or sulphuretted hydrogen; but the clot had less contractility, and yielded a smaller amount of serum, especially when arsenite of soda or cyanide of potassium had been added. M. Gauthier considers his experiments fatal to the idea that the coagulation of the blood is in any degree a vital act, a theory which had indeed already sufficiently vanished. He thinks that the red corpuscles yield to the serum carbonic acid, and that that is the determining cause of the coagulation. He does not appear to have made any special experiments to determine this point, which should easily be settled. The theory is hardly consistent with some of the known experimental facts.

AN "UNHEALTHY AREA."

To the Holborn District Board of Works belongs the honour of having taken perhaps the first active step towards applying the provisions of the Artisans' Dwellings Act to one of the "unhealthy areas" within the metropolis. Some days ago a deputation from the Holborn District Board of Works, as the local sanitary authority, attended at the Metropolitan Board of Works to inform that body that the medical officer of health of the Holborn district had officially reported that a considerable number of houses, courts, and alleys within an area bounded on the north by Portpool-lane, on the south by Holborn, on the east by Leather-lane, and on the west by Gray's-inn-road, are unfit for habitation, and dangerous to health. It was moreover stated that the construction of these houses and streets, as well as their condition, was such that the evils complained of could only be remedied by an improvement scheme for the re-arrangement and reconstruction of the streets and houses within the area. The Metropolitan Board is asked to pronounce this area as *unhealthy* within the meaning of the new Act, and to take such measures as may be necessary to enforce the provisions of the Act with reference to the area. The importance of this application may be judged when it is stated that the area referred to consists of nearly 14 acres, including no less than 24 courts and alleys in Gray's-inn-lane, which is now one of the most densely populated spots in London. About 230 houses and more than 1000 families would be temporarily displaced if the improvement scheme is sanctioned. It was incidentally mentioned that some of the wretched alleys within this area were only 4 ft. wide. The result of this attempt to put the provisions of the Artisans' Dwellings Act in operation will be watched with much interest.

THE LATE BISHOP THIRLWALL.

It is not, we believe, generally known that this eminent and enlightened divine was remarkable in showing in his early childhood intellectual attainments of a very high order; and it is well to advert to this here, if only to show the falsity of the doctrine that such early ripening of the mind tends to weaken or impair the vigour of the intellect before the prime of life. The deceased prelate lived to the age of seventy-eight, retaining his highly-cultured intellect almost to the last, having enriched the world with many valuable productions, of which his History of Greece and translation of Niebuhr are perhaps the best known. Yet, when he was but "three years of age he was taught Latin, and at four read Greek with an ease and fluency which astonished all who heard him." Our quotation is from the preface (written by his father) to a volume of Essays and Poems published in 1809, and purporting to be written by Connop Thirlwall when but eleven years old. In this remarkable juvenile precocity the late Bishop of St. David's resembled his friend John Stuart Mill, who has recounted in his autobiography that he began to learn Greek when he was three years of age, and Latin when he was eight. Each has left his mark upon the age in which he lived, and each has thoroughly fulfilled the promise thus held out in his earliest childhood—the one became one of the foremost scholars of the time; the other one of the greatest of modern philosophers.

BROMIDE OF CAMPHOR.

A brief monograph on the physiological and therapeutical properties of bromide of camphor—a powerful and somewhat uncertain remedy introduced to the notice of the profession chiefly by Bourneville and Lawson—has recently been published by M. Pathault, of Paris. Experiments on animals have shown that it reduces the number and force of the pulsations of the heart, and causes narrowing of the calibre of small arteries by its action on the vaso-motor centres—conclusions somewhat at variance with one another, since whilst it has an inhibitory effect on the central organs, it acts as a stimulant to the sympathetic in the peripheral portions of the vascular system. It is also stated to have a lowering influence on the rate of respirations and on the temperature of the body, the reduction in the latter respect being rapid and very marked (as much as 3° C. in an hour). Dr. Pathault has found that the elimination of the bromide by the urine begins within six hours after administration of the drug, and is not completed for two days. On the nervous centres it acts as a hypnotic, and also gives rise to clonic convulsions and muscular tremors. Dr. Pathault gives myographic tracings from frogs poisoned with the drug, and shows that they differ from those produced by strychnine (with which it had been commonly compared) in resembling almost entirely the physiological tracing. The drug has been given in doses varying from four to sixty grains with variable results in cases of delirium tremens, insomnia, chorea, infantile convulsions, hysteria, epilepsy, neuralgia, and in some affections of the genito-urinary organs.

THE FREEDOM OF UNIVERSITY EDUCATION IN FRANCE.

FOR some time past the cry in this country has been, as regards medical education, "One-portal," but this end is still far from being attained. A change in the contrary direction is now advocated in France, and a multiplicity of portals may be created. It remains to be seen how far the free faculties of medicine will be able to compete with the five now existing, Paris, Montpelier, and Nancy being the old ones, Lyons and Toulouse those recently and officially instituted. We know that in this country there is a wide difference between certain schools of medicine and certain licensing bodies; the same distinctions will probably spring up in France when free faculties are founded in various parts of the land. Judging from the past, no great advantage will be derived from private undertakings of this nature. The promoters will be anxious to get pupils and disposed to make the obtaining of diplomas as easy as possible. Such was, in fact, the case in France in former times—namely, before 1792. At that period there were seventeen faculties, of which seven only had any, and merely local, importance. Good teaching was only found in Paris and Montpelier, and when any doctor of other faculties wished to practise in Paris, he was obliged to undergo a fresh examination in that capital. The provincial faculties were held in so little honour that the time spent in them counted only half when the student repaired to Paris. These provincial faculties competed with each other who should grant diplomas on the lowest terms, and it may be guessed whether the rejections were frequent. It is to be hoped that such a state of things will not be reverted to.

HEALTH OF KENSINGTON.

DR. T. ORME DUDFIELD, medical officer of health, has just issued a Report on the Health of Kensington for the four weeks from June 27th to July 24th, 1875, to which is added a special report on the subject of scarlet fever. The deaths from this disease were 11 in number, or 5 above the corrected average during the last 10 years. With one exception, all the fatal cases occurred in children between the ages of three and nine years, and in streets wholly inhabited by the poorer classes. Alluding to the disinclination of the parents of affected children to report the circumstances, and to other causes of difficulty in procuring information of fresh outbreaks, Dr. Dudfield refers to a fatal case that had been attended by a non-qualified practitioner. The child died at the end of the second week, and the existence of scarlet fever in the house only became known on the registration of the death. The two rooms occupied by the family contained seven persons. Successively the father and two children contracted the disease, and were removed to hospital. The rooms and clothing were disinfected, and the mother and two remaining children were reluctantly compelled to leave the house; but no sooner had they done so than the elder child fell sick, and was sent to hospital. On the day following the burial of the deceased child another family of nine persons left the house. They have been traced, and two children found to be ill. These have been isolated and, as far as practicable, separated from the rest of the family. Among the requirements in sanitary legislation, Dr. Dudfield thinks that none is more needed than power to provide quarantine for the apparently healthy members of poor families in which infectious disease has broken out. From inquiries among the medical practitioners resident in Kensington and other sources of information, Dr. Dudfield concludes that scarlatina is not generally prevalent, that it has not shown a tendency thus far to spread widely, and that the rumours in regard to the fatality of the disease have been, to say the least, much exaggerated.

WHAT IS THE VALUE OF A MEDICAL OFFICER OF HEALTH?

IN a health-resort like Leamington we should at least expect to find a proper value put upon everything appertaining to its sanitary condition and organisation. At a recent meeting of the Town Council, however, a discussion took place on the subject of the reappointment of the medical officer of health to the borough which shows that at least some of the members have a very inadequate idea of the duties which now devolve upon the medical officer of a borough like Leamington. It appears that Mr. Baly, of Warwick, has satisfactorily filled the post of medical officer of health to the borough of Leamington for two years, at an annual salary of £50. Finding, however, that the duties of the post had considerably increased of late, Mr. Baly, in offering himself for re-election, asked for a larger stipend. It was accordingly proposed that the salary of the medical officer of health should be increased to £80. An amendment was proposed to the effect that the salary should be £70, and that Mr. Baly should also be appointed borough analyst, at £10 per annum. Mr. Baly, however, declined this appointment. Another member then expressed his opinion that the increase from £50 to £80 was too large, and proposed that the salary should be fixed at £60. To the credit, however, of the Town Council, the original motion was carried; and we cannot but think that a town like Leamington, with little short of 25,000 inhabitants, is to be congratulated on securing an efficient medical officer of health for £80 per annum. The health of Leamington has of late been very satisfactory, as the annual death-rate from all causes during the three months ending June last did not exceed 16·9 per 1000, and the rate from zymotic diseases was as low as 1·0 per 1000.

MOLLUSCUM CONTAGIOSUM.

THIS interesting and by no means infrequent skin affection has long been debated by dermatologists. Some, as Hebra, deny its right to the term "contagious"; but the majority of writers, at least in this country, adduce ample evidence in favour of its being communicable by inoculation. Nor is there unanimity of opinion as to its pathological nature. Many hold it to be an affection of the sebaceous glands; others, as Virchow, not being able to detect any true fatty materials in the characteristic softened contents of the little growths, believe they arise rather from the hair-follicles. There are again others who, thinking to assimilate the contagiousness of the affection with its pathogenesis, affirm it to be parasitic, and have described certain large fungus-spores (molluscous bodies) in the contents of the growth. Dr. C. Boeck, of Christiania, in a recent paper (*Viertkljahresschr. für Dermat. ü Syph.*, 1875, part i.), shows that none of these views are correct, but that the idea propounded by Retzius as to the seat of affection being in the rete Malpighii is the correct one. Retzius, however, thought the affection was parasitic, and here Boeck differs from him. In the paper from which we quote, the learned Norwegian dermatologist describes fully the histological characters of the molluscous tumour, and shows conclusively that the characteristic contents are formed by retrogressive changes occurring in the cells of the deep layer of the epidermis, the so-called "molluscous bodies" being nothing else than modified epidermal cells swollen and altered by peculiar refractile substance, neither of fatty nor of lardaceous nature. He has never found this change in other conditions, as in comedones or acne pustules, but it is constantly present in this disease; the contagious property of which, he thinks, may be explained either by the self-multiplication of the diseased cells when transferred to other individuals or by their setting up, by "action of contact," similar changes in the part to which they are transferred.

THE REGISTRAR-GENERAL'S QUARTERLY RETURN.

THE combined effect of the low temperature during February and March, and the more than usual variableness of the weather during April, caused the death-rate during the second quarter of this year to exceed the average. The annual rate of mortality during the three months ending June was equal to 21·9 per 1000, instead of 21·4 as in the corresponding quarters of the ten years 1865-74; it was, moreover, higher than in any spring quarter since that of 1866. The excess of deaths during last quarter was confined to those of infants aged under one year, and of persons over sixty years of age. The most satisfactory feature of the return is the decline of deaths from the principal zymotic diseases, which were equal to an annual rate of 2·6 per 1000; the rate from these diseases in the corresponding quarter of the five years 1870–74 was 3·1 per 1000. Although 4063 deaths in the three months were referred to scarlet fever, this number showed a further decline from those in the two preceding quarters, which were 8562 and 5050. The manufacturing and mining populations of Lancashire and Yorkshire again showed the highest death-rates from scarlet fever and other forms of zymotic disease; this is due in great measure to the large proportion of urban population which these counties contain. The health of Leeds and Sheffield has recently shown a marked improvement, but in many of the smaller manufacturing towns and mining villages of the north there is the strongest evidence of the need for sanitary reform. The zymotic rate, which was but 1·2 per 1000 in Suffolk and Hertfordshire, was 3·4 in Nottinghamshire, and 4 5 in the East Riding of Yorkshire. The fatality from typhus and enteric fever continues to decline in England and Wales, especially in large towns.

SUDDEN DEATH AFTER THORACENTESIS.

M. ERNEST BESNIER, physician to the St. Louis Hospital of Paris, brought before the Medical Society of the hospitals, the case of a lady aged forty-three, who was attacked with pleurisy and effusion. There was much weakness; the medical attendant became alarmed, and called M. Besnier in consultation. The patient was very fat, and as dyspnœa was considerable, it was resolved to evacuate the fluid. Everything was carefully prepared, the patient placed herself cheerfully on the side of the bed, and the trocar (No. 2 of Mathieu's apparatus) was introduced through a rather thick layer of fat. The escape did not occur at once, but the trocar being freed from obstruction, a horribly fetid pus flowed into the receptacle of the apparatus. From ten to twelve ounces had been obtained in about two or three minutes, when the patient was observed to turn deadly pale, and ceased to breathe. In spite of all the known means of resuscitation she could not be revived. M. Besnier, in the absence of a necropsy, thinks that the slight wound determined an *arrest of the heart;* and he pointed to the extremely rare occurrence of gangrenous pleuritic effusions.

COMPULSORY VACCINATION AND THE KEIGHLEY GUARDIANS.

THE Keighley guardians, who have been served with a writ of mandamus from the Court of Queen's Bench calling upon them to give directions to their vaccination officers to prosecute all persons within the union who refuse to have their children vaccinated, have also been served with a side-bar rule calling upon them to make a return to the mandamus within eight days. This was served upon two of the guardians, but the board has since refused, by votes of eight against six, to make a return. They also refused at a former meeting, to give directions to their vaccination officers to prosecute the defaulters. The fifteen or twenty thousand people who have the misfortune to have such guardians of the public health as this board, are entitled to the commiseration of all sensible communities. We shall watch with interest the contest between the Law Courts and the guardians. The question now is elevated into one of the respect due to law and to the law courts. It would serve the guardians but right to depose them from an office the duties of which they refuse to discharge. If other persons holding the same opinion should be chosen in their place, and the population should one day experience the due result of their stupidity, they will be entitled to little sympathy.

HOSPITAL SATURDAY.

THERE seems reason to hope that this institution will prove a little more equal to its purpose this year than it did last. The most gaudy and least defensible part of the Saturday arrangements—that of ladies standing with boxes in the streets supported by boys with bannerets—has so far been more productive than last year. Respectability and strength in this movement can only be secured by the skilful organisation of effective means for the reception of systematic payments from working men towards the support of the hospitals of London by which they and their families are so enormously advantaged. For the working men of London to give £5000 or £6000 to these institutions is altogether inadequate, and implies discredit either to them or to those who undertake to represent them in the collection. None will be more happy than we if the result of this year's Hospital Saturday should prove to be a worthy sum.

THE SANITARY CONDITION OF MAIDSTONE.

WE wish we could agree with Mr. Barham, the medical officer of health for Maidstone, who, in his last published monthly report relating to June, stated that on the whole the public health of the borough during that month might be considered "most satisfactory." After deducting three deaths that occurred in the County Lunatic Asylum, the deaths in the town during June were 37; of which 6 resulted from scarlet fever, 2 from measles, and 1 each from small-pox and enteric fever. Thus 27 per cent. of the deaths resulted from the principal zymotic diseases; which is hardly consonant with a satisfactory condition of health, although it is stated that the annual death-rate from all causes during the month did not exceed 18 per 1000. It appears that the deaths in Maidstone during May had been 60, and the decline to 37 deaths in June; which constitutes, perhaps, the only satisfactory feature in the June report, the fatal cases of scarlet fever having decreased from 9 in May to 6 in June. This disease was described by Mr. Barham, in his June report, as being prevalent throughout the town, although in a mild form; and enteric fever is also described as considerably prevalent. The medical officer states that the "stowage of manure and rags has much increased in the town within the last few years, and that he has received frequent complaints of the smell arising therefrom." We cannot agree with his opinion that, where this stowage takes place in spaces "well open and exposed to all winds, it cannot come under the denomination of a nuisance injurious to health." This unsound decision affords but poor satisfaction to those who are being poisoned by the stench from these manure stores. We shall be very glad to hear that the health of Maidstone shows an improvement upon what its health officer describes as its present "most satisfactory" condition.

LUNACY.

The Twenty-ninth Annual Report of the Commissioners in Lunacy, which has recently appeared, shows that at the beginning of the current year 63,793 persons were registered in England and Wales as being of unsound mind, an increase of 1766 as compared with the previous year. In the course of the last seventeen years insane paupers have increased from 16·14 to 23·55 per 10,000 of the population, and private patients from 2·53 to 3·09 per 10,000. The Commissioners remark that a large proportion of patients in the county and borough asylums consists of chronic cases, "which might be adequately provided for in well-organised workhouse wards." Remarks are also made as to the difficulty that exists in inducing boards of guardians and medical officers to carry out the improved dietary scale for imbeciles and lunatics recommended by the Board.

The percentage of recoveries of the insane in the county and borough asylums of England is 37·90 per cent. In the provincial licensed houses the average for the last year was 29·86 per cent.

OVERCROWDING AT LIVERPOOL.

Dr. Trench, medical officer of health for Liverpool, has presented to the corporation of that town a valuable report as to the means that should be adopted to carry out effectually the provisions of the Artisans' Dwelling Act. Liverpool was quoted by the Home Secretary in introducing the Bill as one of the towns specially requiring reformation, in that it contains a vast number of close courts, with cellar or underground habitations, and small houses placed back-to-back, nearly all of which are entirely unfit for human habitation. Dr. Trench does not, however, recommend wholesale demolition, inasmuch as such a plan would, until new houses were constructed, force decent families to leave small, self-contained houses, even in badly-constructed courts, "to seek shelter and herd with the improvident and vicious in those dens of misery in the low sublet districts of the town." Subletting appears to be one great evil at Liverpool, leading to all sorts of indecency, as one of the necessary results of overcrowding.

TRINIDAD.

The Trinidad Medical Board lately presented a very graceful and complimentary address to Thomas Murray, Esq., Doctor of Medicine of Edinburgh, and member of the Trinidad Medical Board, on the occasion of his completing fifty-five years of arduous practice in his native island. We gladly join our congratulations to those of the Trinidad Board on a feat so creditable as that of fifty-five years of honourable practice. Dr. Murray responded to the address in very beautiful and cordial words, and spoke of the better prospects of the profession in Trinidad, owing to the increased encouragement offered by successive Governors. Another great improvement, he said, is the appointment, on its present footing, of a Surgeon-General, who forms a tie between the Government and the profession.

ABSORPTION THROUGH THE SKIN.

Wolkenstein, from experiments made with frogs, cats, rabbits, and mice, finds—1. That the skin is permeable to dilute but not to concentrated watery solutions. 2. An increase in the temperature of the solution augments the absorptive capacity of the skin; and, in fact, the amount of fluid absorbed stands *in limine* in direct relation to its temperature. 3. In young animals the skin absorbs better and more quickly than in old animals of the same species. 4. Hair and wool interfere with the rapidity of absorption. 5. A few alkaloids are capable of being absorbed and giving rise to the peculiar symptoms of their toxic influence.

The report of the Board of Management of the Huddersfield Infirmary, read at the annual meeting of the governors of the institution last week, was of a satisfactory character, financially and otherwise. The balance-sheet showed an increase of £730 in the receipts as compared with last year, the total income being some £160 over the expenditure. A very welcome gift from Mr. G. Brooke was announced, in the shape of a set of medicated baths—a remedial accessory the need of which is, we are glad to know, becoming very generally recognised by the managers of hospitals, as well as by those who are interested in the efficiency and completeness of these institutions. The Convalescent Home at Meltham, in connexion with the infirmary, appears also to be in a flourishing condition, 503 patients having participated in its benefits during the year, an increase of 119 over the number admitted within the previous twelve months.

The action brought, in the Vice-Chancellor's Court, by Mr. Hope, V.C., against the Romford Local Board for non-fulfilment of contract with regard to the sewage of the town, has resulted in a compromise to refer the case to Sir J. Bazalgette, the engineer of the Metropolitan Board of Works, to report to the Court, and say whether the works as they then existed were sufficient to deliver to the plaintiff all the sewage of the town of Romford, or such part thereof as should fall by gravitation into the outfall sewer which, on the 16th of May, 1870, conducted the sewage into tanks constructed on the farm, in the lease of that date mentioned, and, if not, whether anything and what ought to be done or left undone to give him such benefit.

In London last week 2362 births and 1422 deaths were registered. The former exceeded by 106, whereas the latter were 388 below, the average numbers in the corresponding week of the last ten years. The annual death-rate from all causes, which in the two preceding weeks had been equal to 22·4 and 22·3 per 1000, further declined to 21·5. The rate was 21 per 1000 in the west, 21 in the north, 20 in the central, 20 in the east, and 24 in the south groups of districts. The deaths included 1 from small-pox, 44 from measles, 87 from scarlet-fever, 6 from diphtheria, 63 from whooping-cough, 23 from different forms of fever, and 137 from diarrhœa.

In a report to the Liverpool Health Committee it was stated that 226 deaths were registered in the borough last week, showing the large decrease of 120 compared with the corresponding week of last year. The deaths from zymotic diseases numbered 53, being 71 below the average. Altogether, the health of the town is at the present time in an extremely satisfactory condition.

Surgeon-Major Alder, who was charged with the murder of Lieutenant Walker at Fort Hubberston, having been tried at the Pembrokeshire Assizes, has been acquitted on the ground of insufficient evidence.

In consequence of the nuisance caused by cargoes of condemned fish being sent down the river in barges, and so polluting the atmosphere on the river and about the banks, the Corporation of London, as the sanitary authority of the port, have issued a special official notice on the subject, requesting all persons interested to give immediate information to the medical officer of health, at the Port Sanitary Offices at Deptford, in order that these foul cargoes may be seized and destroyed under his supervision.

The Local Board of Sevenoaks had a meeting on Saturday to consider a report from Dr. Baylis, the sanitary inspector, as to the condition of the town. Dr. Baylis stated that forty cases of fever had come under his notice, and two new cases had just been reported to him. The fever arose from the existence of cesspools and the bad construction and filthy condition of certain buildings. He recommended the extensive use of disinfectants, which the board ordered to be supplied as required.

Meteorological statistics show that the month of July was unusually cold and wet. The mean temperature at the Royal Observatory, Greenwich, was 59 deg., and 2·6 deg. below the average July temperature in 103 years. The amount of rain in the month was 5·3 inches, measured on sixteen days, which exceeded the average rainfall of July in 59 years by 2·8 inches. The rainfall of the first seven months of this year amounted to 15·1 inches, and was 1·8 inches above the average.

The bust of Dr. Hughes Bennett, in white marble, was formally presented to the Senate of the University of Edinburgh on Monday, immediately after the ceremony of "capping," in the presence of a large assemblage of distinguished visitors and professors and officers of the University.

In the House of Lords on Tuesday the Commons' amendments to the Lords' amendments of the Public Health Bill were agreed to, and their lordships resolved not to insist on any of their amendments which were distasteful to the lower House.

The death, at Paris, is announced of Dr. Marchi, one of the most celebrated physicians of Italy, who saved the life of Prince Humbert, when attacked by dangerous illness about ten years back.

Sir Alexander Armstrong, K.C.B., Medical Director-General of the Navy, commenced this week his annual tour of inspection at Haslar and other naval hospitals.

We regret to announce the death, in his seventy-third year, of Mr. John Churchill, the medical publisher.

THE NEW FELLOWS OF THE COLLEGE OF PHYSICIANS.

At a meeting held last week, the following gentlemen were elected Fellows of the Royal College of Physicians of London:—

Adey, Charles Augustus. M.D. Edin., St. Leonard's.
Burder, George Foster, M.D. Aberd., Clifton.
Corfield, William Henry, M.D. Oxon., Bolton-row.
Falls, William Stewart, M.D. St. And., Bournemouth.
Fearnside, Henry, M.B. Lond., Preston.
Matterson, William, M.D. St. And., York.
Monckton, Stephen, M.D. Lond., Maidstone.
Montgomery, James Barclay, M.D. Glasg., Penzance.
Ord, William Miller, M.B. Lond., Brook-street.
Semple, Robert Hunter, M.D. St. And., Torrington-square.
Shepherd, Augustus Burke, M.B. Oxon., Seymour-street.
Thorne, Richard Thorne, M.B. Lond., Inverness-terrace.
Tuke, Daniel Hack, M.D. Heidelberg, Falmouth.

THE ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

The forty-third annual meeting of the British Medical Association has been held during the present week in the illustrious city of Edinburgh. The number of members who made their way to the University, the head-quarters of the Association, on the morning of the 3rd instant, was unusually large. At the University a reading and writing room, an inquiry office, post, telegraph, and cab offices, and refreshment-rooms—in fact, everything calculated to enhance the convenience and comfort of visitors—had been prepared. The local secretaries were Dr. J. Batty Tuke, Mr. John Chiene, Dr. McKendrick, and Dr. Bishop. At eleven o'clock the opening service was held in St. Giles's Church, which was filled to overcrowding. An appropriate sermon was preached from 1st Peter ii. 17., by the Rev. W. Lindsay Alexander, D.D., who eloquently discoursed on the honour which we owe to all classes and conditions of men. At one o'clock there was a private meeting of Committee of Council, and at half-past two a meeting of Council.

About three o'clock in the afternoon the members began to congregate in the Free Church Assembly Hall, in order to be present at the first general meeting, and to hear the President's address. When the President appeared, amidst tremendous cheering, at half-past three, the hall was full. The business was commenced by the retiring president, Dr. Copeman, of Norwich, who, in a brief speech, thanked the members of the Association for the honour they had conferred upon him by electing him president. Dr. Copeman then resigned the presidential chair to Sir Robert Christison, who was received with the loudest acclamations. A vote of thanks having been accorded to Dr. Copeman for the able and courteous manner in which he had filled the office of president, he was made a vice-president of the Association on the motion of Dr. Sibson.

Baillie Tawse, in the absence of the Lord Provost, in an able speech, welcomed the Association in the name of the City Corporation, the members of which were present in their official robes.

These preliminaries having been gone through, Sir Robert Christison delivered his address.

THE PRESIDENT'S ADDRESS.

After some words of welcome, and an expression of gratitude and thanks for being selected as president during the meetings of the present annual session, Sir Robert Christison took for the subject of his address—"What sound reason exists for a fundamental change in medical education and medical examinations?" Disclaiming all intention of undertaking to treat it methodically and in whole, he meant to view the question from a quarter whence it had not yet been looked at. "I propose," said the President, "to give you historically some insight into the school life of one of our chief seminaries of medical education, in the hope that there may be found in its history some safe guidance in the present somewhat wild struggles of our profession to improve itself, to redress what seems faulty, and to frame, if possible, a masterpiece of medical examination and precursory study. In singling out for this end the medical school within whose walls we are to be assembled, I do so from no vain-glorious pride in the school to which I have myself for many years belonged, but because—firstly, I know its history, constitution, and work best; secondly, being here, you will probably take some interest in a subject with which most of you are but slightly acquainted; and, thirdly, because it is most surely worth while to inquire in the present conjuncture into the causes which have led the medical department of the University of Edinburgh, situated in an outlying quarter of the kingdom, to become for wellnigh a century, with little interruption, the most populous medical school in the British Islands.

"The University was founded by James I. (of England) in 1582. In the following year, the Faculty of Arts was started at once by the teaching of six of the seven subjects now required for graduation in that faculty; and the Theological Faculty was instituted at the same time by the founding of a chair of Divinity. A Law Faculty was not initiated till a few years after the commencement of last century; that of Medicine had its beginning in 1685, through the energy and influence of three of the most remarkable medical men of the day in Scotland—Sir Andrew Balfour, Sir Robert Sibbald, and Dr. Pitcairn.

"Botany seems to have been their first object. Fifteen years earlier Balfour and Sibbald created the rudiments of a botanic garden, one object of which expressly was to introduce into Scotland the cultivation of foreign plants yielding medicinal products, which, in those days of not easy intercourse among nations, were not readily got when wanted. Our modern Royal Botanic Garden of twenty-seven acres, too small for its 340 students, had its origin in 1670 in a little plot of ground close to Holyrood Palace, measuring forty feet square, in which, nevertheless, were reared no fewer than 900 plants. The site was soon transferred to a large garden, where now flourishes the City station of the North British Railway. But one relic survives in a fine yew now adorning the garden in charge of Dr. Balfour and Mr. Macnab, twice transplanted successfully after becoming a considerable tree, and proving its own age by the *modulus* of De Candolle, according to which it must be above two hundred years old. The success of the Physic Garden was so great, owing to the fostering care of its promoters and the ability of its first keeper, James Sutherland, originally a clever young gardener, that, in 1676, an Act of the Town Council of the city, then the founders and patrons of professorships, established in Sutherland's favour a Chair of Botany in the University. But, for some unknown reason, the Act was not given effect to, so that a second Act of Foundation became necessary to make him effectually a University Professor in 1695. In the meantime Sibbald had influence enough to obtain also in 1685 the establishment of a Chair of Medicine.

"It is a fact not unworthy of notice, as throwing some light on the early history of medical education in this country, that, in every other university of what is now the United Kingdom, there existed for a long period of years only a single professorship of Medicine. Oxford had its professor of Medicine first in 1535, and no other medical professor for nearly a century. Cambridge got its Chair of Medicine in 1540, and no other till 1702. Dublin began in the same way in 1637, without addition till 1783. Of the Scottish Universities, Glasgow was slow to undertake the teaching of medicine, its professorship of Medicine having been founded in 1713, of Anatomy in 1718, of no other branch till 1807. St. Andrews had its first professor of medicine in 1722. Singularly enough, the University of Aberdeen has the merit of having anticipated all others, even Oxford and Cambridge, and been the very foremost in the United Kingdom to possess a chair of Medicine. Under the name of Mediciner, King's College, Aberdeen, had a professor 'before 1522' (Calendar, 1875), probably so soon as 1505. In the younger Marischal College there was a professorship of Medicine in 1701, but no support to it till a chair of Chemistry was erected in 1793.

"Plainly, then, it was understood in all these universities for more than a century that one man was competent to educate students for the medical profession. Sir Robert Sibbald and his coadjutors were the means of establishing, for the first time in Britain, three professorships of Medicine in the University of Edinburgh. Thus they may have introduced the valuable novelty of dividing its special branches among special men. But it is not now known how they taught, or even that they did all teach. Their teaching, at all events, made no graduates; for there was no medical graduation in Edinburgh till 1726, forty years almost after their appointment.

"The University of Edinburgh was not the only theatre in which efforts were early made to institute medical education in the Scottish capital. The Royal College of Surgeons also appear to have given it encouragement. But the College of Surgeons never established a School of Anatomy and Surgery. I should add, perhaps, that lectureships, in default of professorships, were appointed for several branches of medicine by the Universities of Glasgow and Aberdeen; but not till last century was far advanced. In Edinburgh alone were the roots of a medical school, in the true sense of the word, fairly planted in its University so early as the end of the seventeenth century, and brought to maturity in the first quarter of the century following.

"The school of Sibbald and Pitcairn was but a beginning, and probably not very successful; but soon afterwards matters took the right direction towards a separation of subjects, by the establishment of a lectureship on Anatomy in 1705, and the foundation of a professorship of Chemistry in 1713. In fact, it was not till the appointment of Alexander Monro *primus* to be professor of anatomy in 1720, that the University School of Medicine put on a shapely form, and entered upon its career of prosperity.

"Monro has his place in history as one of the European anatomists of the last century. But anatomy was not his sole gift by any means. Highly educated, favoured by his conspicuous office, which he entered when only twenty-three, and bringing to the task he had set himself an intimate knowledge of the organisation of the schools of Paris and Leyden, he won the confidence of men of station and influence. He not only soon placed the University Medical School on a sound and prosperous footing, but likewise mainly created the Royal Infirmary. In the University he found ready to his hand a chair of Chemistry and a chair of Botany; there was also the old chair of Medicine, capable of being moulded into the fitting shape of Practice of Physic. Anatomy and surgery were his own province. In 1724 was added a chair of Theory of Physic, which then embraced physiology, pathology, and therapeutics. In 1726 midwifery was also provided for, and materia medica was early taught by the professor of botany in the winter, botany itself occupying his attention during the summer months. Thus the whole round of medical science and practice came to be skilfully partitioned, each subject being taught separately; surgery, too, by one of the six professors, and materia medica by another of them. This arrangement—extensive, complete, and harmonious for the times—was carried into effect very long before anything of the kind was attempted at any other university, or, indeed, so far as I can discover, in any other school of medicine in the United Kingdom. Several of these professorships have been subdivided since that time. But all branches were taught from the first, and the only new creations in the University have been those for natural history, medical jurisprudence, and clinical medicine and surgery. The first of these is a general rather than a medical chair. In the establishment of the three others, the University of Edinburgh took the lead by a long way of all other British schools, as it had done in the organisation of a school, complete, according to the times, immediately after 1720.

"I have said that Monro was mainly instrumental in originating the Edinburgh Royal Infirmary. In 1728 subscriptions enough had been got to set on foot next year a small hospital. A larger one having been subsequently built and gradually extended, a Royal charter of incorporation was obtained in 1736. Monro evidently had designed from the first that the hospital should be devoted not more to the cure of the sick poor than for the education of students of medicine. The culmination of the fabric, so far as education is concerned, was the inauguration of the teaching of clinical medicine in 1748 by Dr. John Rutherford, Professor of the Practice of Physic. The hospital managers espoused warmly the cause of clinical teaching. In consequence, Rutherford was joined ere long by some of his colleagues; and in 1756, as we find from the infirmary records, clinical instruction was given by Rutherford; Whytt, Professor of Theory of Physic; Cullen, then Professor of Chemistry; and Monro himself. The coalition of four such men in training up a medical school from its infancy was a mighty element of success. Priceless, too, was its own organisation, as fashioned by the genius of Monro." The President then went on to trace out the success of this new University School of Medicine from the time that Monro himself began his lectures on anatomy and surgery in 1720, with 57 pupils, up to the present date. So far as the relations of Ireland to the Medical School of Edinburgh is concerned, he said, it has accomplished the isolation aimed at by the Irish people in weightier matters: in medical education Home-Rule has been attained effectually.

The President then proceeded to inquire into the causes of the great prosperity of the University, the organisation of which has been so very different from the not less prosperous universities of England. From the leading particulars in the history of the medical department of the University during the last 150 years, he proceeded to draw attention to the inquiry proposed at the outset: Whether this narrative may not yield some useful lessons to the many who, with praiseworthy zeal, have lately proposed to alter and innovate largely in medical education and medical examinations.

"I submit that the Edinburgh School of Medicine—as proved alike by the great afflux of students, and by the multitude of men of mark trained in it who have held a high professional place in all parts, and in all public medical offices, in the British dominions—has thus been so eminently successful, that its system deserves great consideration; perhaps for guiding other schools, but certainly in dealing with itself. Nevertheless, there are some essential parts of that system which the opinions of some recent reformers, if acted on, would abrogate or dangerously injure.

"Take, for example, the duration of the courses of lectures. The ordinance of the Universities' Commissioners of 1860, on medical education, which by statute has the force of an Act of Parliament, requires that the courses of instruction during the winter session shall extend to at least one hundred lectures, and during the much shorter summer session to fifty. But a late eminent authority, whose name, were I to mention it, would be received with universal high respect in his department, used to sneer at this regulation whenever it was spoken of, and held up his hands in horror at the idea of the poor student being compelled to listen to one hundred lectures in a session. Other men, taking more precise views of this subject, have urged that such full courses may be reduced to fifty, as sufficient at least for any branch except anatomy. It has even been propounded in print that some branches of medical instruction, which in Edinburgh are taught in one hundred lectures in winter, may be advantageously disposed of in thirty-five summer lectures in London and the English county schools. At length, one confident writer in a weekly journal made the discovery that it might be better if certain of these subjects were not lectured on at all; and in one sense of the question I am disposed to agree with him.

"It is true that these thorough reformers go further, and contemplate the substitution of practical teaching and home study for lectures. Reading, however, at the student's home forms an essential ingredient equally of both systems of tuition. It is scarcely necessary to say, that every student who means to profit fully by a course of lectures, possesses works of reference for enforcing, recalling, and expanding what he hears in the lecture-room. But reading cannot be advantageously substituted altogether for what he hears. The poet's maxim,

'Segnius irritant animum demissa per aures
Quam quæ sunt oculis subjecta fidelibus,'

applies to the relative influence of the description and the exhibition of visible things or events, not to the respective effect of hearing and of reading about them. On the contrary, the theatre, the pulpit, and the bar prove familiarly to all how impressive are the words of a speaker compared with the words in a book.

"Moreover, in teaching the medical sciences, demonstration to the eye may generally be employed to aid demonstration through the ear. Our predecessors of last century seem not to have been so fully aware of this as we ourselves are. Anatomy, chemistry, botany, and natural history were indeed taught by them with that aid. But during my four years' course of study the professor of the practice of physic did not so much as once make use of a specimen, a drawing, a diagram, or a black board. So was it with his colleagues of clinical medicine, of physiology and pathology, and even of materia medica. It was not till my predecessor, Dr. Duncan, succeeded to this chair in 1821, that demonstration by specimens and experiment was added to lecturing. But now, in every branch of medical instruction, the eye is appealed to as well as the ear. Wisdom is let in at both entrances, and at small additional expense of time, and no pecuniary cost to the student.

"In order that lectures may be attractive, however, they cannot be very brief. When too much curtailed, they must consist mainly of bald principles and naked facts enunciated with the scantiest garnishing, and thus all zest is lost. No observant lecturer can fail to notice that, so long as he is dealing with abstract principles, general statements, bare descriptions, and dry facts slightly associated, it is difficult to secure the attention of his students. It is quite different when his discourse is argumentative, when he supports his propositions by suitable instances, when his description of objects is made clearly diagnostic by comparison with others, and, above all, when he is under no restraint in the copiousness of illustration by examples. The attention of his hearers is then fixed, and if he can prop up a conclusion by a well-chosen, telling case of his own, all heads are raised and all ears on the alert to take in his information. This blending of general statements with richness of illustration it was which constituted the charm of some of the lecturers in my younger days, and eminently of Dr. James Gregory, Professor of the Practice of Physic. Gregory was the most captivating lecturer I ever heard. His course of a hundred and twenty lectures was attended to the last day with great regularity by classes of from three hundred to three hundred and sixty students. Every one acquainted with the history of British medicine during the present century knows how powerful an impression Gregory made on medical practice throughout the whole British dominions. Right or wrong, he was the apostle of bloodletting, which stood the test of half a century's experience. The sway of his doctrines was owing entirely to his lectures, and to the publications of his pupils, for he himself never published on any branch of the practice of medicine. But would Gregory have found scope for his rare talent in the *beau ideal* course of fifty or eighty lectures—the hobby of present-day reformers? Let Gregory himself supply the answer. In his annual course of a hundred and twenty lectures he overtook only two-thirds of his subject.

"Those teachers and guardians of youth who lament, and those students who complain, that it is found irksome to attend lectures at the schools where the very short courses of instruction I refer to have been adopted, will now probably understand the cause. Some teachers at these schools have themselves made the discovery. It will probably be also understood why, when tuition by systematic lectures has been made so very barren on any subject, I agree with those most radical of all reformers that it is well to have on that subject no systematic lectures at all.

"Practical instruction cannot take the place of systematic instruction. For, in the first place, the latter is an essential preliminary to the former; and, secondly, the student's period of study is much too short for his acquiring an extensive acquaintance with the great leading details of all the required subjects by practical study.

"Systematic instruction is an essential preparation for practical study. This no man, I presume, will deny. But the more thorough the systematic instruction, the better the preparation. Take anatomy for example. Practical anatomy is studied longer and more thoroughly by the general mass of students now than fifty years ago. But I have never understood that the systematic teaching of it has been curtailed on that account at any of the great medical schools. On the contrary, in consequence of the extension of anatomical science, what is called 'anatomical demonstrations'—which formerly meant daily demonstration by the professor or his 'demonstrator' of what had been done during the day by each dissector in the practical rooms—has been converted at several schools into an additional course of systematic lectures on anatomy, carried on at a second hour. How far ought other branches of medical education to be treated differently? What of chemistry, for instance, the importance of which to medical science and medical practice is becoming more and more apparent every year? Chemistry was the next science after anatomy which was taught effectively in this University in the practical way. For many years Dr. Hope offered his students no opportunity of practical instruction. At length, in 1823, the teaching of practical chemistry was begun by his assistant, Dr. Anderson; it has been improved, and ever since continued, by Anderson's successors in office; it has been long adopted by every extra-academical lecturer on chemistry here; and it was considered by the Universities' Commissioners of such value to the medical student that it was added by them in their Education Ordinance of 1860 to the curriculum of study for medical degrees. Dr. Hope, I have said, gave no opportunity for practical study. But, as I well know from personal experience, his course of 136 lectures on systematic chemistry was so complete, and so fully illustrated by never-failing experiments, that no diligent student ought to have found difficulty in taking up any branch of the subject practically, after learning the use and the handling of instruments and apparatus. I found none, at least, when subsequently at Paris

I embarked in what were then the highest objects of chemical research—the analysis of the gases, the proximate analysis of vegetable poisons and medicines, and the elementary analysis of nitrogenous organic bodies. No such thorough preparation, however, could have been attained by the brief systematic course of sixty or eighty lectures proposed by the practically-minded of the present day. The introduction of practical chemistry into the University qualifications for medical degrees was not the cause of the reduction of our winter session from six to five months; and I am much mistaken if that change has not been found to cramp the systematic instruction given by the Professor of Chemistry, to limit unduly the branches included in it, and to curtail the experimental illustrations of those which he is able to overtake. A third branch of medicine in which practical study is imperative on candidates for graduation in the University of Edinburgh is pharmacy. It is enjoined to be taken at the laboratory of a hospital, dispensary, or private practitioner, and it cannot now be studied in the University. But provision will soon be made for supplying that defect; and when it is made, the course of lectures on materia medica may be relieved and shortened by being confined chiefly to therapeutics. A fourth branch is midwifery, in which practical instruction may be taken at a hospital or dispensary, or by attending the private practice of a medical practitioner. But besides all these subjects, botany, physiology, pathology, and natural history have been successively made the subjects of practical instruction by their respective professors. In several of its branches, surgery, too, is now taught practically, and there is no reason why medical jurisprudence should not be taught in like manner. Great success has attended such instruction in every branch of medicine in which it has been undertaken—in none more than in physiology. Hence some have proposed to add several of these newer practical studies to the imperative list, especially physiology and pathology.'

"But now we meet in the face a formidable question. Trusting to found on the theory of practical education a mode of escape from one horn of a dilemma, are we about to rush on another precisely similar? Can the usual time-limit of medical study admit of such diversified practical training? Systematic instruction cannot be given up, were it merely as preliminary to practical instruction, and it cannot be given in short space. Whatever extent of it be held to be necessary, no part of it can be curtailed without practical instruction being extended to supply the loss. But for every detail thus withdrawn from the former, treble or even quadruple the time is required to teach it by the latter method. This will be acknowledged by all who are conversant with both—by teacher as well as by pupil. In the same space of time the lecturer can go over in his systematic course, even with the addition of demonstrations and experiments, three or four times the amount of details which the student can overtake in any plan of practical study. It is a mere hallucination, then, to suppose that the latter can materially take the place of systematic lectures. In every way in which we look at the question with the eye of experience, it will be seen that in a sound system of medical instruction systematic teaching must be the principal means, and practical teaching ancillary only. Care must therefore be taken that the practical method be not extended beyond due bounds. These considerations lead me to observe that many labour under an exaggerated and mistaken idea of the extent to which the medical sciences can be acquired by the practical method in the course of a student's curriculum of study. In fact, some teachers, in consequence of the same mistake, have erred, I think, as to the kind of practical instruction which they have endeavoured to impart. Some aim at covering a large extent of ground, and thus making the student acquainted practically with a great variety of objects. By this way the knowledge acquired is necessarily superficial, and consequently fugitive, besides proving not very serviceable afterwards in actual practice. Others, confining the attention to comparatively few objects, teach familiarity with instruments and other means of research, the principles of scientific investigation, and skill and invention in inquiry. The information so gained, though limited as to objects, is precise, profound, lasting, and such as enables the pupil to study any other similar subject with accuracy and success. The one method crams the student with surface knowledge, much of which he soon forgets. The other trains him to research, and teaches him, in short, how best to acquire knowledge for himself. The latter surely is the real object of school instruction. But it is apt to be lost sight of by modern theorists, who seem to think that the purpose of education at a medical school is to furnish the student with all the professional knowledge he needs, and to turn him out an accomplished physician or surgeon. I wish practical teachers would turn their minds to this question. For my part, I entertain considerable doubts of the real utility of those courses of practical instruction which aim at embracing a great variety of matter. In regard to practical chemistry, for example, I well remember the time when a highly popular course of the kind was given in this school, and that on one occasion I found my four clinical clerks, who had all gone through it, were unable to make a filter, to pour a fluid securely into it, or to boil wine with confidence in a glass tube. The conclusion I come to on the whole question of medical training is that the most efficient system consists of full systematic lectures and auxiliary practical instruction carefully chosen and limited. Such has been the system pursued in the University of Edinburgh, and hitherto the University of Edinburgh has been eminently successful.

"I have purposely reserved for separate notice the most important of all practical training, clinical study, because it is somewhat peculiarly circumstanced. Clinical teaching ought to comprise lectures, demonstration of actual cases, and examination on them. This constitutes practical instruction auxiliary to the systematic courses on the practice of physic and practice of surgery. But by practical clinical instruction is meant something more: every student ought also to acquire such experience as is gained in the office of clinical clerk in an hospital. Unless he has served as clinical clerk, or in a similar capacity in a dispensary or with a private practitioner, so as to have been brought into close contact with cases of disease, and in a position of some responsibility for the knowledge and treatment, he is not yet prepared for entering upon independent medical practice. Herein lay a great mistake of our predecessors. The majority of their graduates and licentiates were sent forth into independent practice, possessing no more practical acquaintance with disease than was got from clinical lectures, and, indeed, at most schools in the kingdom, with no more than they could pick up for themselves by what was aptly called 'walking the hospitals'—that is, looking on as they best could, without lectures, beside demonstrations, examination on cases, or any other help or guidance whatsoever. But now the rule, at least at this University, is for the graduate, if not already trained as clinical clerk, to seek that or some similar opportunity of thorough practical study before taking advantage of his newly-acquired legal right to settle in independent practice. If this rule be so general—almost, indeed, universal, as I suppose it to be, here at least, there is, perhaps, no call to enforce it by educational statute; and there is the serious objection to a statutory rule, that it is one very difficult to define and enforce without inflicting frequent hardship—owing to the impediment which is sure to start up in the way of all important additions to medical study, the limit of time allowable for a student's education. But if this, the most valuable of all his practical training, is to be demanded of all medical aspirants, it may be effected in one of two ways. The first mode is to induce the student to commence his professional studies, not with the month of October or November, as is usual, but in the beginning of the previous May, so as to take his Botany and Natural History before commencing his statutory four years' curriculum. It is gratifying to find that very many of the students of the University of Edinburgh are now doing so of their own accord. If they could add to these Chemistry in the preceding winter of preliminary education, so much the better. The four usual 'Anni Medici' would thus escape crowding; and the last six months might be left nearly clear for a clinical clerkship. This clear half-year could be obtained with certainty, if the present courses of lectures were better co-ordinated. Some are too long; several are too short; and at least two, Anatomy and Practice of Physic, are much too short. But by altering the sessions, from a winter period of five or six months and a summer period of three months, to two equal periods of four months, with an interval of one month for holidays or graduation examinations, I am convinced that almost all our courses of lectures would be materially improved, none injured, and the concluding six months left free for clinical clerkships, or other practical training of the same kind.

Under the present system four years of study are rather too short a period. Under a different system they would generally suffice. But it would be said, why not lengthen the period of study at once to five years? This measure was a favourite one in the General Medical Council during the first years of its life. But no more has been heard of it since the following objection was mentioned. The additional year cannot be subtracted from the years for preliminary education, but must be added to the four professional years; and, therefore, licence or graduation must be postponed to the age of twenty-two. But if a man may join the Church, the Bar, or the Senate at twenty-one, why not the Profession of Medicine too, especially as many years must elapse before he can attain to remunerative practice. Moreover, a careful examination of the books of this University proves that, although of 200 graduates in two successive years, four-fifths took at least five years of medical study, and graduated at a greater age than twenty-one, the remaining fifth who graduated at twenty-one, after four years of study, comprised three-fourths of those who passed their trials with distinction. Why then should these forty young men be prevented from beginning professional life early, and thus be defrauded of the advantages of the talent with which they had been blessed by Providence? And why in the profession of medicine alone? Another way of securing the advantage of some such practical study as a clinical clerkship affords, is to require it to be taken, as I have said that a great proportion of the students of the Edinburgh school actually do take it—immediately after graduation or licence, and before settling in practice for themselves. In that case let it precede registration; for which purpose remove the present statutory prohibition against entering certain subordinate offices before being registered. But it may be said that there ought also to be a further examination. By all means. I think there is an insane rage for examinations at the present time. But there can be no great objection to a clinical examination at any period of life Every new case of disease which a medical practitioner has to treat is a clinical examination to him. Of course a young man, who has just passed through the required training, and who professes himself competent to enter upon independent practice, may well be called on to prove his competency by examination—that is, by exemplifying what his practice is to be. Such examinations might be fitly conducted by any of the present examining boards. Or, if a Government pass be advisable, as many believe, to serve as a check on these boards, and for a greater surety to the public, there is here offered a simple and effectual opportunity for interposing a separate and independent board, to secure the sole object for which a conjunct board, or Government board—which are one and the same thing—can be reasonably demanded—viz., to see that a young man is competent to enter upon the practice of medicine independently on his own account.

"Thus I approach the last topic with which I propose to occupy your attention at the present time. It is one about which the general sense of this Association and my humble opinion may hitherto have been not much in accord. But I entertain hopes that the case may prove different before we part. For many years past there has been outcry in our Profession, and murmuring even among the general public, against a multiplicity, or even a plurality, of examining boards for licensing entrants into the medical profession. Many have seen, as they think, such evils in that system as even to have advocated the establishment of a single board to supersede, or at least to override, all those now existing. Out of this feeling has been engendered the scheme of a conjunct board or boards, to be made up of examiners selected from the existing boards, and whose province it should be to examine all candidates whomsoever, and necessarily either to supersede existing examinations, or to repeat and multiply them. At first measures of this kind were very popular—very much so with the General Medical Council, and not less so, I believe, with some men of note, members of the British Medical Association. For my part, however, I very early took quite a different view of the proposed revolution. There was no opportunity of stating in the General Council what could be said against it before my retirement from that body. But I have raised my warning voice since then in several other Councils, and also in correspondence. Whether from this cause, or more probably through the influence of calm reflection which time has allowed to all public bodies concerned, the result has been that every licensing board in Scotland is now opposed to the change; and in the two other divisions of the kingdom, where all boards seemed about to rush into one another's arms for the purpose of being conglomerated and individually extinguished, zeal has of late been greatly cooled in this direction, and there has arisen a prudent hesitation in coming to closer quarters. Let us then look a little into the whole matter with the aid of the light which time has thrown upon it. At a period not very distant some licensing examining bodies were too short-handed. Others were undoubtedly too facile. Corruption even was charged; with what justice it is needless now to inquire. To correct these faults was one of the well-understood objects of the Medical Act of 1858, and one of the duties of the Medical Council which that Act has founded. Has the Act been found to fall short of its purpose in this particular? Certainly not. The Council may have set about the work of reforming the examinations rather slowly, but they are not to be blamed on that account. They had much besides on their hands. They were too numerous to deliberate promptly. It was well that they should gain public confidence before approaching the most delicate of their tasks. Their powers were thought not clear enough, nor sufficiently direct for vigorous action. Nevertheless much good has been done in several directions; and now the Council appear to have set about the duty of controlling examining boards with determination. It is well that they have done so in the present crisis; for the results will supply, if I mistake not, valuable advice in the present conjuncture. I have gone carefully over the reports of the able inspectors who have finished this year's duty, and I find that they pronounce various examinations to be all but faultless—that they point out an important fault in the examination of one of the most powerful medical bodies in the kingdom, a fault which, I doubt not, will be at once mended—and that they declare one board so far behind in duty, that both the examination and the Board of Examiners must be remodelled. The Medical Council therefore now know that they can command the services of inspectors who will report to them the truth without fear or favour. The Council are also already made aware of insufficiency existing in some quarters. But have they power enough to correct? Hitherto they have carried all their other measures by persuasion merely. But if in the present matter persuasion fail, have they the power to employ force? Such power is given by statute; but it is roundabout. A charge must be laid against the accused board before the Privy Council, who may, or may not, confirm it and enforce the remedy. The statute has been thought in this respect too feeble. It must not, however, be treated as such until it is tested by actual trial, and the trial has not yet been made. If the statutory power prove too feeble when fairly tried—for example, against a powerful recalcitrant adversary—I see no reason why the Medical Council should not receive direct power to enforce its mandate, subject to appeal to the Privy Council. Such appeals are apt, indeed, to be costly. But, perhaps, so much the better; there will be no appeal by a board not quite satisfied of being in the right. But the Medical Council and the public now know, also, that no small number of the examining boards of the country are without fault. Therefore they can point to models from which defective boards may take example, nay, must do so. Therefore, too, they may say to Government and the public, and the members of this Association who have taken a strong and laudable interest in the reform of examinations—'In regard to the former bodies, there is no call for any legislative interference. In respect to others, we know what is to be done with them; let us try whether we can do it with the powers already entrusted to us; it is probable that no further legislative aid will be required.' This is a plain and reasonable policy. Surely it is right that the Medical Council be not disturbed in their present efforts and perpetually paralysed at the opening of every Parliamentary session by new Medical Bills, founded on mere theory, proposing to revolutionise and overturn what has gradually arisen as adapting itself to the wants and wishes of the nation. One condition, however, must be admitted to be indispensable. As every physician ought to be educated in surgery, and every surgeon in physic, so every board, which singly qualifies a man for registration, must possess the power and the means of examining on all required subjects, medical and surgical. The Universities, with few exceptions, enjoy this advantage. The three corporate colleges in Scotland have found no difficulty in acquiring it by combining together. In London, however, the medical corporations have hitherto been unable to unite, or mutually lend examiners, for reasons the cogency of which it is not easy to comprehend, but which assuredly ought to be put an end to one way or another. If these bodies cannot combine, why should they not obtain by charter the right to do, each of them, that which the Edinburgh University lately accomplished without either difficulty or delay under its new constitution granted by Parliament in 1858? It possessed twelve Professors specially qualified to examine, each on a special subject, and in addition three examiners from without, who examined on any of the subjects. But the Professors saw the advantage of having twelve non-professorial examiners, specially qualified like themselves on each of the twelve subjects of examination, to do duty *pari passu* with themselves. In two or three months the legal forms were gone through, and twelve first-class men obtained—five in Edinburgh, two in the Scottish counties, five in England, and three of these in London. You will now understand what I meant by the 'elasticity' of this University. There is, in fact, scarcely any right and wise thing wanted which may not be attained under its constitution, provided the cost be forthcoming; and that, too, is seldom long in being supplied. Why should not each of the important Royal Colleges of England possess, for their efficiency, the same power with the University of Edinburgh, of borrowing all round them, completing their examinations, and each qualifying singly for admission to the register in the fullest sense of a practitioner entitled to practise according to his education? Why not indeed, but for mutual jealousy and the antiquated fondness for keeping up a bygone distinction—a distinction which really exists no longer, except for the limited few who stand at the top of each branch of our profession. Nevertheless, these bodies are said to countenance at the same time a complicated project of conjunction for themselves, and unhappily for all their sisters too, and for all the Universities likewise, which threatens to imperil the prosperity of all, and the very existence of several of them. This is the erection of a joint examining board for the whole kingdom. Much has been said in Council and in print in praise of some such measure. But what has been uttered hitherto has been addressed to the general question only; and no one, so far I am aware, has looked either to details or consequences. Those who do so will not be much enamoured with it. A favourite idea with many is that there should be, for entrance into the medical profession, what they call a 'one portal system,' a single-door scheme, a single examining board, to subject every candidate in the kingdom to one uniform system of examination. In England no one has yet done more than announce the theory, which, however, has met with a favourable reception. From Ireland there was sent over a few years ago a scheme of the kind, which went so far as to recommend an examining board of twelve, and for each a fee of ten guineas a day. There are, however, ten subjects of examination, for each of which we must have two examiners sitting constantly together, or twenty in all. Let us see what will be the amount of their work. From a return, for which I am indebted to the kindness of Dr. Hawkins, registrar of the General Council, the annual additions to the register may be taken in round numbers, for the last three years, at 900. To these may be added 60 for those who, going to the colonies or for other reasons, do not require to register. On calculating the returns of all examinations for two years, as annually published by the General Medical Council, 240 rejections must be added, in order to make up the total number of persons to be annually examined by this single board. Long experience warrants the conclusion that the oral examination of 1200 candidates will occupy each examiner at least 400 hours. Experience also teaches that, for a moderate continuity of time, four hours of such monotonous uninstructive occupation are as great a strain upon the human mind as most persons will sustain. Further, large experience shows that the setting, watching, perusing, and judging written examinations will take each member of the board 184 days, on the assumption that 200 candidates are set at work at one time; but as this sort of labour is of a more contemplative kind, we may ask each examiner to give eight hours a day to it. Thus his whole annual duty will occupy 124 days, so that, deducting Sundays and half-holiday Saturdays, he will be engaged, if continuously, for five entire months. As such lengthened absorption of time involves the surrender of almost every other ordinary professional object, and the members of such a board must be men of the first water in their several spheres, to secure public confidence the proposed remuneration will not prove so unreasonable as it might appear at first. The cost of salaries would thus consequently be 27,000*l.*; and secretary, clerks, halls, offices, and examination expenses would certainly raise the whole cost of the single board to 30,000*l.* annually. What return is to be got for all this inordinate outlay? In the first place, as the scheme charges the cost upon the candidate, each of them will have to pay at least 25*l.* for his examination. The candidate, at least in Scotland and Ireland, will be subjected to the additional expense of travelling a long distance to the seat of examination, which may be presumed to be destined to be London. Thirdly, one half of them will have to wait for their turn three, four, or five months after being ready for examination on completing their studies. Fourthly, all this trouble and expense are in addition to what are required for their degree from a University or their license from a corporation. Corporation licentiates, indeed, may be relieved of part of the expense, and all the superfluous annoyance of a double examination, by adopting the provision of a different joint scheme to be mentioned presently; which provision would make the single-door examination sufficient for obtaining also the license of any of the incorporated bodies. It will be seen by-and-bye whether the corporations can safely thus give up their own examinations. But in the meanwhile what about the Universities? The single-door examination, being the winding up of the general Medical Council's plan of medical study, which is avowedly a minimum, cannot be a major examination. If not also a minimum, it must at least be minor. The examination of the Universities, however, generally is, and must be made at all of them, a major examination; and the Universities cannot give it up for one which is lower. Thus would arise the absurd anomaly, that, after paying smartly in time and study for a high title obtained through a high examination, the University candidate would be called on to undergo another and minor examination, and to pay another large fee for the superfluity. Fifthly, it is unnecessary to add in the present place the risk of a single national board of examiners, conducting a minor examination, over all the kingdom, without rivalry, becoming the fountain of mediocrity in all things medical, in education, in professional qualifications, and in scientific advancement. This result of centralisation and loss of freedom was so luminously put by Mr. Lyon Playfair years ago in the House of Commons, in his speech on one of the great education questions, that few can have forgotten the deep impression which it made upon the country. So much or the candidate. The case of the examiner should also be ooked to. I presume this single door, or national board, like the General Medical Council, would consist of a half from England and a quarter each from Scotland and Ireland. Hence one-half of the members would have to pass annually almost half the year from home. I have not hitherto met with an examiner of some experience who did not find his duty in no long time irksome. A fortnight of such work four hours a-day would try the powers of most men of the stamp of which such a board ought to be composed, the duty is for the examiner so monotonous and so unimproving. Five continuous months of such mental torture would probably land half the examiners in a lunatic asylum. In order to meet some of these evils, it might perhaps be proposed that the work should be divided between two, three, or any other necessary number of similar boards. The cost would be the same, the labour would be endurable, and the convenience of candidates would be consulted. The expense to candidates, however, would remain the same, and the vexatious absurdity of a double examination. Moreover, what would become of the one-portal theory with more than one board? The written questions might be made the same for all, but not the appraisement of the answers. As for the oral examinations, it is evident that the differences could not be slight, and might be quite as great as now. Changing the examiners, and centralising their place, but leaving a plurality of boards, could tend but little towards uniformity of examinations. Such a scheme, in short, is no one-portal system at all; and it differs in no material respect, even in details, from the scheme of conjunct boards which has been for some time before the General Medical Council and the licensing bodies of the kingdom. According to that scheme, all the Universities and all the Corporations are to unite in forming three boards, one for each division of the kingdom. In England, however, the labours of a single board would be intolerable for the examiners; and their sittings would be too protracted for the reasonable convenience of candidates. In Ireland and in Scotland the duration of duty would be less, yet still too great; and in Scotland the hardship on candidates would be severely felt, because all the school-sessions come to an end at the same time, and consequently the candidates of one school, instead of being examined there at once, as now, would have to wait till the other schools set the examining board free. The work of such a conjunct board could not be done to the satisfaction of the schools and the country with less than three or four sets of examiners for England, three for Scotland, and two for Ireland. This so-called conjunct scheme has therefore some disjunctions; and it has no alliance to the device of a single board. In order to escape as far as possible the absurdity of double examinations—one for license or graduation, and another for registration—a complex plan of equivalents and exceptions has been proposed under this scheme. The Corporations are to accept the examinations of the Conjunct Board for their licenses, and give up their own examinations altogether. The Conjunct Board is to receive as equivalent to to their own the University examinations on the fundamental medical sciences. The University examinations on practice, such as Physic, Surgery, Midwifery, Pathology, Therapeutics, Medical Jurisprudence, are not to exempt graduates from the examinations of the Conjunct Board on these subjects; but graduates so re-examined are to be let off easy in the matter of fees. Why University graduates should be exempted from the operation of the board in one class of subjects, and not in others, it is not very easy to perceive. The University examination is, or ought to be made, a major examination on every subject alike. Why a second, and minor, examination should be requisite for security of the public is to me at least a profound mystery. Another part of the conjunct scheme is that the candidate whose aim is a Corporation licence shall receive one on passing his trials. For this favour the Corporations are to divide among them a large proportion of the fees. That most ticklish of all points, their respective shares, has wisely not been mooted hitherto. But this much we know. The Corporations will receive large fees without taking the slightest trouble for them—a provision which looks odd when thus plainly expressed, but which is necessary to compensate them for the loss of fees now received for their own examination and licence. The reasonableness of some such compensation is apparent to us of the present generation; who will therefore easily submit to it. But our followers in the next generation, probably as restless and fond of change as ourselves, will be apt to take a different view, when they find themselves severely mulcted for little or nothing—for no privilege whatever—for an empty title only. It is mere vanity to set forth as an equivalent the advantages of museums and libraries; which no one can enjoy who is not a resident of one of the three capitals. In no long time a new agitation will arise upon the most hateful, but most potent, of all themes—a money question; and it is easy to foretell the result. In fine, the Universities may withstand the threatened revolution. But the Corporations will be in danger of becoming mere clubs. Universities are a necessity for the highest walks of professional education in every civilised land. Corporations are not so situated. In the whole Continental kingdoms there is not, and there never has been, anything approaching in constitution to our British Incorporated Colleges. Some perhaps may be disposed to ask—'Why, then, should Corporations exist in any country?' and a rumour has reached us here that this question has been actually whispered among some vigorous reformers in the South. But I apprehend that such a question will find no resting-place in this Association or in any other public medical body; and I mention it merely to give a little cogency to my fears, that, if the Corporations part with their present important privilege, and the most important of the duties for which they were chartered—that of examining themselves the candidates for their licences—they may find they are opening the door for the question being seriously raised at some future period. Why, then, venture on a complex plan of examination difficult to carry out, far from sure to attain its object, fraught with hidden dangers, and opposed by some of the chief professional bodies concerned? Why not rather take advantage of the present system—itself, indeed, complex enough, but nevertheless the gradual product of the wants and the wishes of a free people, not, therefore, to be lightly set aside? Why not correct it, and improve it through means which the Legislature has not long ago put into the hands of our Profession for the very purpose? The present entrance-door to the Medical Profession is not really, though nominally, a University, a Royal College, an Apothecaries' Hall, or a Faculty of Physicians and Surgeons: it is an examination. There is no reason I can discover why the examinations of all these bodies, numerous though they be, may not be brought up to a reasonable standard of equivalence, now that the Medical Council have put forth their strength towards that end. Let their endeavours have a fair trial. Should the result prove unsatisfactory owing to insufficient control, support them in obtaining more direct powers; and allow time for further trial. This, surely, is a wiser course than to rush upon untried treacherous ground, and daring measures entirely novel, which, though on the surface they promise reform, at bottom threaten revolution. Allow me, in conclusion, to add a brief word or two on the general question. In this kingdom three denominations of practitioners are provided by education and examination:—(1) The ordinary class of general practitioners in town and country; (2) high-class physicians and surgeons, who practise chiefly in cities and large towns; and (3) an intermediate order, educated on the footing of the highest attainable education for the greatest possible number, and whom circumstances may attach, some to the first, some to the second class. The Corporations provide the first class by their licence, and most of them, by means of their Fellowship, enable licentiates to pass into the second class, if they please. The two great and old English Universities, through means chiefly of a protracted education, and the London University by elaborate examinations, aim at producing the second class, at least in physic, ready-made, so to speak. The founders of medical education, as well as their successors, in the three Scottish University schools, and likewise, I think, in those of Ireland, have aimed at supplying the third class, by supplying the highest education attainable by the greatest number. It is no part of my present undertaking to settle which of the three educational aims is the most important. They are all highly so. It is as little a part of my present undertaking to inquire which of the three objects have been satisfactorily reached by the several bodies entrusted with them. All have undoubtedly been more or less successful, and none can be charged with failure. But I claim for the Scottish Universities, and eminently for the University of Edinburgh, that they have attained the object for which they were destined, by supplying to the greatest number the highest education of which that number can take advantage; that, also, they enable men of superior original talent or industry to go out from their schools with high qualifications, not inferior to those of the graduates of any of the English Universities; that these results flow from their system of education and examination, the fruit of long educational experience; and that their elasticity is such as to render it easy for them to adapt themselves to the progress of knowledge and of public opinion. It is well known that the Universities' Commissioners, under the Act of 1858, took infinite pains to effect such adaptation at that time. I have put before you the remarkable result. Surely it is not too much to ask that the Universities of Scotland shall not be disturbed by further and doubtful innovations during so important an experiment, following recent and serious changes; and I venture to submit that their neighbours may do worse than watch a little longer the experiment going on here before they venture upon dangerous innovations for themselves."

Although the Address was, as might have been anticipated, an able one, there was a general feeling amongst those present that the subject was for that occasion neither appropriate nor interesting. After Sir R. Christison had dilated for about an hour on the history of the Edinburgh University and on its excellences, many unmistakable symptoms of fatigue showed themselves in the audience. One by one the assembly thinned, until at last not more than half of those present at the commencement were left to hear the vigorous onslaught on the proposed Conjoint Scheme, and on the functions of some of the Medical Corporations.

No better manifestation of the high respect that every member of the profession bears towards the venerable President could have been given than that, notwithstanding the tediousness of the address, and the uninteresting nature of the topic to the vast majority of the audience, more than three hundred remained to the end. Those, however, who did stay evidently had a keen relish for the quaint humour of Sir W. Fergusson, who, in one of the best speeches we have heard from him, proposed a vote of thanks to Sir R. Christison. When Sir William humorously remarked that in the brief space of an hour Sir R. Christison had given the outcome of many years of careful thought, the spontaneous and simultaneous movement of all faces towards the clock was simply ridiculous—the fact being that the delivery of the address occupied more than two hours.

Then followed a mighty exodus. Not more than about eighty of the 800 present at the opening remained at the first general meeting. And when it is borne in mind, that even of the eighty many were members of the Council, it will be no exaggeration to say that the meeting was not a representative one.

It was first proposed that, as it was so late, the Report of the Council should be accepted as read, and entered on the minutes. This unparalleled procedure was of course opposed by Mr. Walter Rivington, who moved an amendment that the Report be printed and circulated among the members, for consideration on the following day. This amendment was lost by 31 against 35, the thirty-five against the amendment including the members of the Council themselves.

Dr. Sibson then proposed that the altered bye-laws of the Association be accepted *en bloc* without discussion. In his usual pleasant manner he besought all present to waive discussion and to propose no changes. There were, he said, few differences from the old bye-laws, and anything that appeared undesirable could, he said, be brought up for discussion next year. There were, he confessed, changes made which he was sure would be unmade next year.

Mr. Husband followed in the same strain, and begged the members to take the word of the committee and accept the bye-laws without reading them or discussing them.

To this strange proceeding Dr. Chadwick entered a vigorous protest, as there were several most important questions involved in the bye-laws which he should like to have discussed.

After a little discussion the dominant party gained the day, and the few members who stayed accepted for the great body of the members, without reading them, the altered bye-laws.

After the formal re-election of office-bearers the meeting, which had altogether lasted over three hours, broke up, and the members went home to late dinners.

At half-past nine in the evening the President held a reception in the Music Hall, George-street, where, notwithstanding a very heavy fall of rain, a very large number of the members of the Association and their wives made their way. Upwards of 1600 were present.

At half-past nine on Wednesday morning, the 4th inst., there was a private meeting of the Council, 1875-76.

At the same hour Professor Lister gave demonstrations of antiseptic surgery in the theatre of the infirmary.

The demonstration was an instructive and entertaining one. In it Mr. Lister showed all the various apparatus required in the practice of antiseptic surgery, including the preparations of instruments and dressings, and the precautions to be taken by operator, assistant, and patient. He then illustrated the mode of employing antiseptic dressings.

The first case that was treated was a simple but striking illustration of the practice of antiseptic surgery. A man who had previously been successfully operated on for the removal of a collection of fluid under the deltoid muscles, was admitted with an effusion into the right knee-joint. As the fluid had persisted in spite of the ordinary method of treatment, it was deemed advisable to evacuate the fluid by operative interference. The limb was therefore washed with a solution of carbolic acid (1 in 20), and the atmosphere surrounding the limb was rendered aseptic by means of a carbolic acid spray (1 in 40). A free incision was then made along the outside of the patella with a knife that had previously been lying in a carbolic acid solution (1 in 20). After the divided vessels had been secured with a fine catgut ligature, and all bleeding had been arrested, the capsule was opened and the fluid evacuated. The finger, previously made aseptic, was then passed into the joint to examine its condition, and a band which prevented the free passage of the finger was divided with a probe-pointed bistoury. Two prepared drainage tubes were then put into the joint to ensure free escape of fluid, and the wound was then dressed by means of the protective and well-known gauze with the piece of mackintosh. It may here be observed that in our columns Mr. Lister described the recent improvements in the apparatus employed in antiseptic dressings, and in the mode of using them.

A second case was then shown, in which the ankle-joint had been opened a fortnight previous on account of pain and swelling. When the dressings were removed, the wound was found partly healed, there was no putrefaction, and the original blood was lying in the wound, and evidently undergoing organization, for when it was cut it bled profusely.

In a third case, Mr. Lister had operated twelve days before on the femur in a man for united fracture. The wound was healed where it had been stitched. There was no inflammatory reaction, and everything was progressing satisfactorily. The whole of the limb was fixed in a plaster of Paris splint, and a permanent cure is confidently expected.

At the conclusion of this interesting demonstration, in which all the minutiæ of antiseptic surgery were elucidated and the advantages of this practice fully proved, Mr. Lister was loudly cheered.

The second general meeting of members was held in the Chemistry Class-Room at half-past eleven of the same day.

After some discussion, Brighton was appointed as the place of meeting for 1876, and Sir J. Cordy Burrows was chosen president-elect. An attempt, which seemed at one time likely to be successful, was made to have Liverpool appointed as the place of meeting next year. In favour of this proposition it was urged that whereas many members of the profession in Brighton had petitioned against the holding of the meeting at Brighton, a numerous requisition had been sent from Liverpool requesting that the Association would hold its next annual meeting at that town.

The thanks of the Association were then accorded to Mr. Southam for his services as President of Council. Dr. Falconer, late Treasurer, was elected President of Council, and Mr. Husband was appointed Treasurer.

After some other unimportant business was got rid of, Dr. Oliver Pemberton, of Birmingham, said that he noticed among those appointed to read papers were two ladies, and he presumed they were members of the Association. He did not know by what means these ladies had been made members, but he felt that on a question of that kind the opinion of all the members of the Association should be taken. He therefore moved—"That it be an instruction to the Secretary, between now and the next annual meeting, to issue a circular addressed to every member of the Association, requesting an answer, yes or no, as to the admission of female medical practitioners to membership."

This was duly seconded by Dr. Marshall, who complained that the members of the Association had too little opportunity for the discussion of its own affairs, and he called upon the members generally to insist on their right to take a more active part in the management of the business of the Association.

After some remarks from Dr. Carpenter and Mr. E. Hart, the motion was carried almost unanimously, there being only one hand held up against its acceptance.

Dr. Warburton Begbie then delivered his able address, which we publish *in extenso*. After a vote of thanks had been accorded to Dr. Begbie, on the motion of Dr. Gairdner, who spoke in high praise of the orator's qualities, socially and professionally, the meeting broke up.

In the afternoon the business of the sections was proceeded with.

On Wednesday night the President and Fellows of the Royal College of Physicians gave a *conversazione* at the Museum of Science and Art. The assemblage was large and brilliant, the spacious halls and corridors being well filled. The company on their arrival were received by Dr. Lowe, President of the College, and Mrs. Lowe.

At half-past nine on Thursday morning Professor Lister gave a second demonstration of antiseptic surgery. At ten the third general meeting was held, and while Mr. Lister was addressing a crowded theatre the Council were reading the Report of Committees to almost empty benches, the said reports being received in silence by the audience. At the commencement not more than twenty-five members were present, and the number did not at any time exceed fifty. At eleven o'clock Professor Spence delivered the Address in Surgery, in which he ably reviewed the general progress of surgery.

In his address the President of the Section of Public Medicine referred to the recent attempts at sanitary legislation. He strongly condemned the haphazard manner in which medical officers of health are appointed, and denounced the inequality of the size of the districts allotted to each. He affirmed moreover that the Local Government Board has not yet fully recognised its preventive functions, and expressed his determination to ascertain whether the machinery of the Board is competent to secure the prevention of preventable diseases. He warmly advocated the registration of disease, which he held was of equal importance with the registration of deaths, which, after all, only gave the number of wrecks after the storm, whereas the registration of diseases would indicate the state of the barometer that precedes the storm, so that we should have warning to avert it, or fly from danger.

EMIGRATION.

The sanitary aspects of emigration are so numerous and important that we naturally scan with great interest the annual returns on this subject furnished by the Board of Trade. The exodus of persons from the United Kingdom to the United States and the colonies during the past year exhibits a total decrease of 22·40 per cent. as compared with 1873, the falling off being wholly due to the emigration to North America, attributable to the high rate of wages now given in this country, and also to the commercial depression in the United States. These passengers were conveyed in 664 vessels, 536 of which were steamers, and 128 sailing ships. Of the steamers, 423 went to the United States, 92 to British North America, and 8 to Australia. No mortality returns have as yet been received in respect of the Australian ships, but it is necessary that they should be published, as several epidemics have occurred in these vessels among children. Among 156,776 passengers in steamers to North America, 30 deaths occurred, being at the rate of ·02 per cent., which, taking the voyage at twelve days, is equal to a mortality of 5 81 per 1000 per annum. The 34th section of the Act passed last year to amend the law relating to births and deaths, and to consolidate the law respecting the registration of births and deaths at sea, obliges the master of every British ship, under a heavy penalty, to furnish a return to the Registrar-General of Seamen of every birth and death that occurs on board. It is to be hoped that plain directions are given to the masters enabling them in some sort to classify diseases, inasmuch as the last returns of mortality at sea gave 60 deaths from "natural causes," and 161 from "unknown causes." A total of 33 deaths occurred among 5879 passengers to Australia, being at the rate of ·56 per cent., or, taking the voyage at seventy days, equal to a mortality of 29 per 1000 per annum. The miserable loss of the *Cospatrick* by fire caused the death of 470 persons, but no other casualty occurred during the year, which speaks well for all concerned.

These returns, though compiled carefully and summarised well, are yet very incomplete as regards particulars of what may be called the sanitary aspects of emigration. As we remarked above, no particulars are recorded relative to several epidemics that occurred on board Australian ships last year. It is proper that the causes of deaths, too, should be included in these reports, that special notes should be sent by the medical officers of the ship to the Board of Trade as to the general hygienic state of the vessel during the passage, and the general sanitary condition as regards sickness (without mortality) of the passengers. These notes should be collated and summarised at headquarters, and thus a valuable addition to knowledge in sanitary science afloat would gradually be amassed. We refer, of course, chiefly to Australasian emigrant ships, for the North Atlantic passages are too short to admit of much or precise medical observation. The medical officers of the army and navy, and civil practitioners in charge of convicts, coolies, or army drafts afloat, are all required to keep a very strict diary of the cases under their charge. Why should not this plan be adopted as regards our emigrants, who are in most other respects very well cared for? We are informed that the scales of medicines, medical stores, and instruments required to be carried in emigrant ships are being, or have been, revised and simplified; and that some pains are likely to be taken to ensure that none but registered practitioners shall take service afloat. This latter reformation has been shown to be necessary in consequence of a return submitted to Parliament some few weeks ago, on the motion of Captain Bedford Pim.

All these reforms are in the right direction; but recent revelations and many circumstances that have lately transpired with reference to the Merchant Shipping Bill that has just been "massacred," all tend to show that the Marine Department of the Board of Trade is very much overweighted. Inasmuch as the Board is now responsible for the proper conduct of many matters connected with medicine, hygiene, scales of diet, accommodation of crews, ventilation, antiscorbutics, &c., all of a purely technical character, it is eminently advisable that the political and permanent chiefs should have the continuous aid of a professional officer, to whom all such matters would be referred from the outports, who would conduct all official inquiries, look to the qualifications of ships' surgeons, the condition of medicine chests, &c.; and furnish an annual report, such as we have indicated above, on the sanitary condition of emigrants and emigrant ships, as well as of the mercantile marine.

Correspondence.

"Audi alteram partem."

CHLOROFORM OR ETHER.

To the Editor of The Lancet.

Sir,—I beg to thank you for the very impartial manner in which you have referred to the subject of the relative dangers of ether and chloroform as general anæsthetics. If I have committed any error in publicly calling attention to this important question, I can only urge in extenuation that my object has been based entirely on general and professional good—not on personal interest. I never administer an anæsthetic. I have witnessed death take place from the administration of chloroform more than once, and my deepest sympathies have been with the administrator on such occasions. I am therefore glad, so far, that you have again an occasion to refer to this subject.

There are two points on which I hope you will still further prosecute inquiry, and bring your powerful influence to make each more clear:—The first is as to the actual number of deaths—well authenticated—from the effects of pure ether, and their complications; the second is as to the proper preparation of ether to be used in inhalation.

With respect to your observations in reference to deaths from ether, it appears to me that you have, to some extent, taken too much for granted. After referring to the death, in 1847, at the Hôtel Dieu d'Auxerre, you state that, "In the course of the same year other deaths, assumed to be from ether, and certainly on as good evidence as has been often assigned since in relation to deaths attributed to chloroform, were reported in this country."

Dr. Snow devoted much time at St. George's Hospital to the administration of ether when first introduced. I saw much of his practice, and all who recollect his honest and painstaking method of work will agree with me that he would not have hesitated to publish any fatal results, however much they might have told against his administration of the novel anæsthetic. I write subject to correction, but I have no recollection of any such cases. With respect to chloroform, it is far different.

But let us look practically at the facts as we find them. In 1872 Mr. Haward states (Med.-Chir. Soc. Trans., vol. xlv., p. 7):—"The Committee appointed by this Society to investigate the use and effects of chloroform report 109 fatal cases. In the *British Medical Journal* for July 2nd, 1870, is a table of 18 more cases, and in an appendix to this paper I have given 13 others, not included in either of these collections." I do not stop to inquire how many fatal cases have occurred since that paper was written; suffice it to say, we have here a total of 130 deaths.

What are the results of all we at present know of death from ether? "Dr. Andrews states that in 92,815 cases in which ether was given, in only 4 cases it was fatal. M. Pétrequin, of Lyons, also states that for the fourteen years that ether has been exclusively given in that city there has been no death from it." (Med.-Chir. Soc. Trans., vol. xlv., p. 6.)

Mr. Haward informs me that he has administered ether in more than 700 cases, and has never met with a case which occasioned him the slightest anxiety. Ether has now been administered at St. George's Hospital between four and five years, and in every variety of operation, and, so far as my personal observation goes, I can state that I have not once witnessed a symptom indicative of danger.

There is one advantage in the administration of ether, irrespective of the question of safety, which, I think, has not been sufficiently appreciated. I allude to the benefits derived from the stimulating effects of ether, in cases of severe injury, with great prostration, and in which an operation is requisite—or in any formidable operation. In two instances of amputation at the hip-joint under my care, Mr. Haward, who was the administrator of the ether, observed that the condition of the pulse was better and stronger after than previous to the operation. I always felt anxious while formerly engaged in operating on patients under the influence of chloroform, and more than once had considerable cause for anxiety. Since the use of ether has been established I have had no cause for anxiety, but much satisfaction in its employment.

It is most desirable to obtain all particulars of the conditions attendant on reported cases of death from ether. A late recorded case was evidently due to the employment of ether prepared for local anæsthesia—not pure ether. The case reported in the last number of The Lancet of death from the effects of chloroform would probably have proved fatal under the effects of ether. The patient appears to have had but little spare lung to allow of natural respiration carrying on life, much less could life be safe with any additional interference to the entrance of pure air to the damaged lung. A case related by Dr. Bigelow, in which ether was fatal, would come under a similar explanation.

No one can doubt that ether can be made to kill; but when it proves fatal in a case of diseased or consolidated lung, chloroform would probably prove equally unsatisfactory; but neither anæsthetic should be condemned under such circumstances. But chloroform has destroyed life in the most healthy subjects, often without any warning, and prior to the commencement of the operation for which it was intended. Nor does there appear to be any preliminary symptom by which its unfavourable effects may be predicted. The sudden cessation of the pulse is the only symptom antecedent to death.

With respect to the quality of ether to be used for inhalation, I give no opinion. I am informed that pure washed anhydrous ether should be alone employed. You will do good service by having this point set at rest.

The cost of an anæsthetic should not be of a moment's consideration when safety is placed in the balance. Nor is the difference of time required to produce perfect anæsthesia of any importance, when it is found to be only about a minute or two in favour of chloroform.

Allow me to say that if I have appeared in any degree to have overstated the advantages of ether, I have only reported the results of not a slight observation of its effects, and with a conviction, from such observation, that in the hands of a large number of our profession it is the safest and a perfectly safe anæsthetic. Chloroform, administered by one who possesses the tact, experience, and judgment of Mr. Clover, is reduced in danger to a minimum. It is not everyone who can command his experience and judgment, nor is it everywhere that his method of administration can be adopted. The "rough and ready" method of administration by lint, towel, or sponge must be had recourse to, and thence the danger.

I now take leave of this subject. If what I have said should in the remotest sense serve to lessen the dangers of anæsthetics, or be the indirect means of saving a professional brother from the distress of witnessing a fatal case, I shall be amply rewarded, and the profession generally will have to thank you for having once more brought this question prominently forward.

I am, Sir, yours obediently,

Grosvenor-street, W., Aug. 3rd, 1875. George Pollock.

To the Editor of The Lancet.

Sir,—In your leading article last week, on the subject of the relative advantages of chloroform or ether as an agent for the production of surgical anæsthesia, you represent the question as one which is still open to doubt, and you speak of the existing experience of chloroform as being enormous, and of that of ether as if it were comparatively small. May I be permitted to say, with great submission, that these are views in which I cannot concur, and which appear to me to be entirely at variance with well-established facts.

It may be true, as you allege, that the deaths produced by chloroform are only as one to every two thousand five hundred cases in which it is inhaled; but it is inhaled so frequently that this small proportion amounts to a very serious aggregate. I am acquainted with one surgeon, practising in London, who asserts that he has witnessed *sixteen deaths* from chloroform (all of them, I believe, in the course of operations upon the eye); and with another who has witnessed *six deaths.* The mortality, such as it is, is totally without warning. No experience can foresee in what cases it will occur, no skill can do anything to prevent its occurrence. There have, it is true, been a few instances in which life has been threatened by failing respiration, but in these the patient may always be saved if proper treatment is adopted. The deadly cases are those of syncope, or paralysis of the heart, and this, whenever it occurs, appears to place the victim beyond the reach of human aid.

The loss of one life in two thousand five hundred inhalations would not, I think, forbid the use of chloroform in surgery if chloroform were the safest of our anæsthetic agents, or even if it offered any great practical advantages to the administrator or to the operator. But I contend, first, that ether is in all respects as available and as effectual as chloroform; secondly, that it is *absolutely safe.* I do not believe that it has ever destroyed life, nor do I believe that it has any tendency to destroy it.

With regard to the efficiency of ether, I may say that I finally abandoned the use of chloroform three years ago. Since that time I have performed at least fifteen hundred operations upon the eye at St. George's Hospital, and a smaller number at the Royal South London Ophthalmic Hospital, using ether as my sole anæsthetic. Its administration requires from two to four minutes, and the anæsthesia which it produces leaves nothing to be desired. It has been in use at St. George's Hospital for a still longer period in general surgery; but until Dr. Joy Jeffries, of Boston (U.S.), taught me, in 1872, the proper method of administering it, I did not consider it available for ophthalmic operations. Unless given with great freedom, it does not completely relax the muscular system.

My experience may, I venture to think, be accepted as conclusive with regard to the *efficiency* of ether; and to those who have not found it efficient I would suggest that they have something to learn, as three years ago I myself had all to learn, with regard to the method of administration. On the question of safety, let me remind you that, in speaking of our experience of ether as small, you leave out of sight the colossal experience of our brethren in the United States, who, I believe, use ether almost exclusively, and who have had no deaths from its employment. I will not dwell on this part of the subject, because I have written to ask Dr. Joy Jeffries to favour me with an account of the American experience, which, when I receive it, I will transmit to you for publication. My own cases are, of course, insufficient to establish the safety of ether; but they enable me to say that I do not recognise, in the *nature* of its influence, anything which is calculated to be deadly—nor, supposing common care to be taken, do I see in what mode it could produce death. I fully believe in the correctness of Dr. Joy Jeffries' assertion, that, as long as the patient receives air enough to prevent suffocation, you could not destroy life by ether if you tried. No one who has seen much of the use of chloroform can have failed to recognise the oftentimes deadly tendency of its action.

You say truly, Sir, that deaths from ether have been recorded, but it does not follow that they have taken place. In one recent case, for example, the fluid administered was not ether, but a highly dangerous compound which is used to produce refrigerating spray. In another case, death occurred during an operation on the tongue from the passage of blood into the glottis, and this, although it may have been due to the anæsthesia, could not have been due to the anæsthetic. Among the "recorded" instances there may be some in which the facts are not now ascertainable; but I believe I am correct in saying that wherever the facts have been examined, the case against ether has broken down. It must be understood that I speak of pure sulphuric ether, and of this only.

On the grounds which I have thus endeavoured to set forth, I hold that the use of chloroform in surgery can never be necessary, and, as an inevitable consequence, that it can never be justifiable. I make an exception in the case of young children, for whom chloroform is scarcely dangerous, and I do not refer at all to the practice of midwifery, in which the quantity and method of administration are such as to make surgical experience inapplicable. But I hold that no medical practitioner, merely because he has used chloroform without accident until now, or merely because he has not learnt how to use ether, is entitled to expose a patient to the risk of being the one person who will die, although two thousand four hundred and ninety-nine others may escape.

I am, Sir, your obedient servant,
Wimpole-street, August 3rd, 1875. R. Brudenell Carter.

To the Editor of The Lancet.

Sir,—For the safe and efficient administration of ether vapour for producing anæsthesia, several things are needful to be known and remembered, which are chiefly these:—

1st. That kind of ether should be used which is fittest for the purpose of inhalation, and this is the pure anhydrous washed ether, sp. gr. 720; free from alcohol and water. Robbins's "ether for local anæsthesia" is a dangerous compound for inhalation. It was this last which was used in a case recently fatal at Manchester.

2nd. The ether should be given in such a way that the inhalation may be commenced with a very weak vapour, which, after a few inspirations, can be rapidly increased in strength. If we begin with too powerful a vapour, the air-passages are intolerant of it, and the patient resists the inhalation; but after a few moments' inhalation of a weak vapour, its strength can be increased without inconvenience, and the patient rapidly brought under its influence. I think a cone of felt, covered with thin mackintosh, is the simplest and best apparatus for this purpose.

3rd. Stimulants should not be administered before the inhalation. Ether is itself a stimulant, and can be safely given in cases where there is great depression; but, as Mr. Clover has pointed out, it is very undesirable to have alcohol in the stomach when ether is being inhaled.

4th. Whatever danger may belong to ether has relation to the respiratory function. The breathing should therefore be watched; and, I may add, it is desirable so to place the head of the patient that the saliva (the secretion of which is increased by the ether) may run out at the corner of the mouth rather than into the trachea.

The superior safety of ether over chloroform is not, I think, by anyone doubted, and in my paper read at the Medico-Chirurgical Society in 1871, I pointed out the advantages which it possesses. A greatly extended experience has confirmed the opinions I then expressed, and, with your permission, I would repeat the words with which I concluded that paper. "It has been said that one great advantage of anæsthetics is the mental tranquillity with which a person is enabled to regard the prospect of an operation which is to be robbed of its pain; but I am not sure that this is not often counterbalanced by the dread of an anæsthetic which it is known may of itself prove fatal. It seems to me, therefore, that for this, as for the other reasons I have herein advanced, we should avail ourselves of an anæsthetic so safe as ether appears to be, rather than of one, however much it has to recommend it, to which is attached the danger which unquestionably pertains to chloroform."

I am, Sir, your obedient servant,
J. Warrington Haward.
Montagu-street, Portman-square, July 28th, 1875.

P.S.—May I ask the favour of a reference to the record of fatal cases of ether inhalation mentioned in an article in The Lancet of July 31st, as I am desirous of ascertaining the number of recorded deaths from the use of that anæsthetic. J. W. H.
August 2nd.

⁂ The instances of death either from or presumed to be connected with the administration of ether which we had in our minds whilst writing the article were:—Case recorded in the *Gazette Médicale de Paris* for March, 1848. Jobert, two cases related to the Academy of Medicine, Feb. 16th, 1847. Nunn's case, *Medical Gazette*, vol. xxxix., p. 414. Case in 1847, in which the late Mr. Robinson, of Gower-street, administered ether for an amputation. Robb's case, *Medical Times*, March 27th, 1847. Barrier's case, *Gazette des Hôpitaux*, June 18th, 1853. The Lancet, Oct. 18th, 1873. Ibid., April 17th, 1875. Ibid., July 3rd, 1875. The independent diligence of our correspondent would probably supply him with further similar examples of it were he bent to the task.—Ed. L.

AN APPEAL.

To the Editor of The Lancet.

Sir,—I respectfully invite the attention of the medical officers of the public services to the following particulars of a sad case.

An assistant-surgeon, whose name it is not, perhaps, necessary to give, but which can be given to any subscriber who desires to know it, lost his health in the Crimea, and, after a lingering illness, died from softening of the brain, leaving a widow and five children in circumstances of extreme destitution. This officer's ill-health was not brought on by imprudence or bad habits. Those who have interested themselves in this case, and whose names are given below, know that his habits and conduct were always such as to command the respect of his friends. It must also be added that he made such provision as he could for his family by insuring his life in the Army and Navy Insurance Office, afterwards amalgamated with the "European." It is useless to add that no benefit was derived from this insurance, as this office disastrously failed. When this occurred the state of the assistant-surgeon's health was such that a second insurance on his life was impossible. For several years before his death he supported his wife and family, and met all the expenses of his long illness, on his half-pay of 8*s.* a day. Not having served for ten years, his widow is not entitled to a pension.

It is proposed to raise a sum of money for the purchase of an annuity for the benefit of the widow, who at this time depends on the charity of her neighbours for daily bread for herself and children.

The following gentlemen will be happy to receive subscriptions in aid of this fund:—Major-General Lewis, Shirley, Southampton; Lieutenant-Colonel Begbie, Shirley, Southampton; Dr. Parkes, F.R.S.; Surgeon-General Longmore, C.B.; and Surgeon-General W. C. Maclean, C.B., Royal Victoria Hospital, Netley.

I am, Sir, your most obedient servant,
Netley, 30th July, 1875. W. C. Maclean, M.D.

THE TREATMENT OF HÆMORRHOIDS AND PROLAPSUS BY THE CLAMP AND CAUTERY.

To the Editor of The Lancet.

Sir,—In reply to Mr. James Lane, allow me to state that with regard to the main and most important feature in his "criticisms" of my operation, contained in his communica- for Sept. 2nd, 1865, I made no misrepresentation. The point I wished to call attention to was this, that he had freely given his opinion of, and as freely criticised, a mode of treating hæmorrhoids which he had not once tried himself. In his present communication Mr. Lane confirms this statement of mine, and I must repeat my opinion that when he made these "criticisms" Mr. Lane was not in a position to give any effect to his statements, and I think it was peculiarly unfortunate of him that he did not defer passing judgment until he had had at least some personal experience of this operation. I am glad, however, that a lapse of ten years has made him a wiser man, and more able to give weight to his criticisms, for he tells us that since then he has repeatedly practised the method in question; and as one of my main objects in publishing my papers on this subject is to gain converts, I am greatly pleased at this forward step on Mr. Lane's part.

As I have already laid my experience fairly before the profession, with the reasons which led me to follow this particular plan of treatment in preference to the ligature, I need not discuss the various questions raised by Mr. Lane; but with reference to a remark quoted by him from my original Lettsomian Lectures, to the effect that "It is *not possible* that tetanus or pyæmia can occur after this operation," I beg to state that on a valued friend pointing out this passage to me I withdrew the word *possible*, and substituted for it the word *probable*, in the last edition of my lectures. Of course Mr. Lane has not observed this correction, otherwise he would have acted in a similar manner to one of my most severe critics, Mr. Allingham, who has not overlooked this change in the word, and has pointedly referred to it at page 103 of his book on "Diseases of the Rectum."

With reference to Mr. Lane's hope that I may be converted to the employment of the ligature, I must beg him to dismiss this from his mind—should the anticipation of it give him the slightest amount of pleasure,—for the word *conversion*, as we employ it, means a turning towards something better, a condition of mind and practice we all ought to adopt; but so long as I have the power of discriminating between two courses, I shall certainly never think of going back to the practice of the ligature. After my previous experience of this plan and my present means of the clamp and cautery, I could not conscientiously do so; for I repeat, notwithstanding Mr. James Lane's opinion (and I think I am warranted from my large experience in saying so), that I have repeatedly proved that, as regards the three most important elements of the saving of life, of diminution of pain, and of less prolonged convalescence, the method by clamp and cautery is far superior; and it is a great pleasure to me to hear this statement continually verified by practitioners from the country, and from all parts of the world, who have seen me operate either in King's College Hospital or in private.

I am, Sir, yours, &c.,

Wimpole-street, August 3rd, 1875. HENRY SMITH.

QUACK MEDICINES.

To the Editor of THE LANCET.

SIR,—My attention has been called to a letter written by Dr. O'Neill (accompanied by an analysis of my Blood Mixture), which was published in THE LANCET of the 24th inst. I have no wish to enter upon the question of the correctness or otherwise of the analysis, which, as far as I can judge, must have sadly disappointed Dr. O'Neill, at whose instance it was made; but I am much mistaken if you do not share my opinion that the following facts should be brought to the notice of the readers of THE LANCET, whose columns, though open to *bonâ-fide* discussions of public interest, should be closed against communications having other objects.

On the 21st June last I received from Dr. O'Neill an application for £44 2s. for alleged attendance on myself and my wife in 1864, 1865, and 1866. He at the same time forwarded to me two other bills against relatives of mine, for which I was in no way responsible. His letter admitted that he never previously delivered the account, but stated he had forty-two visits down against me. I am not indebted to Dr. O'Neill, and I hold a bill of his dated Christmas, 1869, to which his receipt is attached, and which does not in any way allude to a previous charge. On the 27th June my solicitor wrote to him denying any liability, but offering to refer the question either to arbitration or to a court of law, *and undertaking to contest the claim entirely on its merits*, and without raising any technical line of defence which was open to me, and which would at once have put an end to Dr. O'Neill's case. A request was at the same time made that the dates and particulars of the forty-two alleged visits should be supplied. No statement has up to this time been delivered, nor has Dr. O'Neill made any attempt to procure a decision on his claim. Instead of taking such a course, he sends his letter and analysis to your paper.

My blood mixture has been advertised for the last twelve years, during the whole of which time Dr. O'Neill has been residing in Lincoln. I have been told on many occasions that he has stated (though incorrectly) that the mixture was made from a prescription of his. But what I wish especially to bring to your notice is that not until Dr. O'Neill has been unsuccessful in his attempts to obtain forty-two guineas from me does he make any effort "to confer a great boon on the profession and a greater boon still on the public at large" by having my blood mixture analysed and the analysis published. From the facts above detailed, your readers will be able to judge whether Dr. O'Neill has induced THE LANCET to "devote some of its valuable space" to the publication of his letter in order to do "great good to the medical profession and to the public at large," or whether his object is not altogether a different one.

I am, your very obedient servant,

Lincoln, 26th July, 1875. F. J. CLARKE.

*** For the sake of fair play we willingly insert Mr. Clarke's letter. But with Dr. O'Neill's motives in writing to us we have nothing to do; and it is very obvious that Mr. Clarke's letter in no way impugns Dr. Taylor's analysis, nor does it affect the only question in which the public are interested—viz., the propriety of administering such an agent as iodide of potassium, not only without medical supervision, but without even the knowledge of the patient himself.—ED. L.

Obituary.

W. J. CLARKE, M.R.C.S.

THE profession in Huddersfield has sustained a great loss by the death of Mr. W. J. Clarke, which took place at Cambridge on Sunday, July 25th, at the age of sixty. His vigour of body and mind, apparently unimpaired, seemed to promise a long life, but for some time he had suffered from occasional attacks of gouty pain. He missed his shooting in the autumn of 1874, and during the winter fell off still further in health. In April he went to Ventnor, and while there had a severe attack of hæmoptysis, which greatly reduced his strength. No structural disease of the lungs, however, could be detected, and he recovered so far as to go on a visit to his brother at Queen's College, Cambridge. Here pleurisy with effusion came on, and, notwithstanding the kind care of Dr. Paget, proved fatal.

Mr. Clarke deservedly held a leading position in Huddersfield. He was for many years surgeon to the infirmary, but, as is usual in the provinces, practised medicine as well as surgery. He was a man of remarkable vigour of character, clear sighted, strong in will and purpose, and thoroughly upright and honest. These qualities, carried into his professional work, made him an excellent all-round practitioner. His diagnosis was solid; he was alive to all the modern advances in therapeutics, but while ready to adopt everything that was valuable, he held fast the best features of the old school of practice which prevailed when he entered the profession. In surgery he was painstaking and cautious, and could show many instances of success in conservative procedure, but when the occasion required he was firm in recommending and bold in carrying out operations.

Mr. Clarke was universally respected, and had many firm friends among the leading men of the town; but it was only during his illness that the extent and depth of the regard in which he was held was known. His sterling worth was appreciated by the educated classes, and the poor had learned to distinguish behind a firm exterior genuine kindness of heart. Only a strong nature could inspire the respect and attachment entertained for him by the unimpressionable Yorkshiremen of the West Riding.

EDWARD WOAKES, M.R.C.S. ENG.

MR. WOAKES was born at Worcester in 1802, and received his early education in that town. Having chosen the business of chemist and druggist, he spent some years in the house of Messrs. Southall of Birmingham. While there he was appointed apothecary to the Birmingham Eye Infirmary, and henceforth became an industrious student of medicine. He subsequently entered at St. Bartholomew's Hospital, and, having passed Apothecaries' Hall in 1828 and the Royal College of Surgeons in 1829, settled in practice at Luton, where he pursued the arduous career of a country practitioner with the energy and zeal peculiar to the men of his day. In 1861 he retired on the dearly earned fruits of his labours, his constitution being greatly impaired by upwards of thirty years of work. Symptoms of softening of the brain set in a few years afterwards, and at length terminated fatally on May 9th, at the age of seventy-three.

Medical News.

Apothecaries' Hall. — The following gentlemen passed their examination in the Science and Practice of Medicine and received certificates to practise on July 29th :—

Bernays, Sydney Adolphus, Acre House, Brixton.
Leigh, Reginald Heber, Aberdare, South Wales.

The following gentlemen passed the Primary Professional Examination on the same day :—

Bouton, George Charles, St. Mary's Hospital; John Bridwell Stelfox, Owens College, Manchester; Thomas Chant, London Hospital; Henry Seymour Atkinson and Thos. Frederick Hugh Smith, King's College; John Alex. G. B. Messum, Wm. Parsons Feltham, and William Henry Gaze, St. Bartholomew's Hospital.

Vaccination Grants.—The following gentlemen have been awarded grants by the Local Government Board for efficient vaccination :—Mr. W. A. Sumner, St. Marylebone, the sum of £149 18*s.* Mr. J. Acworth Angus, Western District of the Newcastle-upon-Tyne Union, £54 3*s.*; Mr. Jonathan Dalgliesh, of the same district, £43 16*s.* Dr. J. H. Gordon, Salisbury, £29 8*s.* Mr. Peter Swales, Sheerness, £25 2*s.* Mr. George J. Berry, Melksham Union, £12 2*s.* E. N. Carless, Devizes Union, £16 9*s.* Dr. C. F. Harding, Whittlesea, £10 11*s.*

The John Propert Memorial Festival.—The Council of the Epsom Medical College celebrated the first festival in pious memory of its founder on Wednesday, 28th July, at the Ship, Greenwich, Mr. Erasmus Wilson, F.R.S., in the chair, supported by the Rev. Dr. West, the head master of the school, Drs. Sieveking, Chas. Hogg, Carr, and Bradley, and Messrs. Burford Hancock, Bransby Powys, Marshall John W. Eccles, &c. Mr. Wilson, in proposing the "Pious Memory of John Propert," remarked that his labours would, as a Godlike work, abide to all time, and teach for ever the blessedness of doing good in life. In proposing the "Health of the Chairman," Dr. Carr said that whilst all the members of the Council laboured to the utmost of their power to carry on the good cause of the College, none had done so much for it as Mr. Wilson, on whose shoulders the mantle of its founder had fallen. To Dr. Chas. Hogg is due the credit of the movement, which the Council and the friends of the College hope to continue annually.

Medical Appointments.

Allen, A. H., F.C.S., has been appointed Public Analyst for the Northern Division of the County of Derby, vice Scott, whose appointment has expired: 21*s.* per analysis, and 42*s.* per day when attending before magistrates to give evidence.

Barkus, B., M.D., M.R.C.S.E., has been appointed Certifying Factory Surgeon for Gateshead, vice Rolf, deceased.

Barron, T. W., L.R.C.P.L., M.R.C.S.E., has been appointed Resident Medical Officer to the St. Marylebone General Dispensary, vice White, resigned.

Bull, W. H., L.R.C.P.L., has been appointed House-Surgeon to St. George's Hospital, vice Bennett.

Callcott, J. T., M.R.C.S.E., has been appointed Assistant Medical Officer to the Durham County Lunatic Asylum, Sedgefield.

Childs, C., L.R.C.P.L., has been appointed House-Physician to St. George's Hospital, vice Sherwood.

Constable, J. J. C., M.D., has been appointed Physician to the St. John and St. Elizabeth Hospital, Great Ormond-street, vice Power, deceased.

Cobe, W., M.B., C.M., has been appointed Medical Officer and Public Vaccinator for the Parish of Muthill, Perthshire, vice Marshall, resigned.

Garraway, E., M.R.C.S.E., has been appointed Certifying Factory Surgeon for Faversham, vice Spyers, deceased.

Goode, H., M.B., has been appointed Public Analyst for the Southern Division of the County of Derby, vice Scott, whose appointment has expired: 21*s.* per analysis, and 42*s.* per day when attending before magistrates to give evidence.

Grace, H., L.R.C.P.L., M.R.C.S.E., L.M., has been reappointed Medical Officer of Health for the St. George Urban Sanitary District, Gloucestershire, his appointment for two years having expired.

Greenway, A. S., M.B., C.M., has been appointed House-Surgeon to the Huntingdon County Hospital, vice Pike, appointed a Medical Officer to the Leicester Provident Dispensary.

Heygate, W. H., M.R.C.S.E., has been appointed Medical Officer of Health for the Crediton Rural Sanitary District, vice Body, deceased.

M'Kenna, W., L.R.C.P.Ed., L.M., L.R.C.S.I., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Carrickmacross Dispensary District of the Carrickmacross Union, Co. Monaghan, vice Tagert, resigned.

Morison, J. W., L.R.C.P.Ed., M.R.C.S.E., has been appointed Certifying Factory Surgeon for the Pembroke District, vice Reid, resigned.

Phillips, E., L.R.C.P.Ed., L.M., L.R.C.S.Ed., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Castletown Dispensary District of the Navan Union, Co. Meath, vice Hamerton, resigned.

Robertson, J., L.R.C.S.Ed., has been appointed Medical Officer and Public Vaccinator for the Parish of Glenbervie, Kincardineshire, vice Henderson, deceased.

Rooney, J., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Kingscourt Dispensary District of the Bailieborough Union, Co. Cavan, vice Langan, resigned, and appointed to the Longford Dispensary District, Longford Union.

Rowe, T. S., M.D., M.R.C.S.E., has been appointed Medical Officer to the Convalescent Home for Orphans, Harold-road, Margate.

Sabb, D. P., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer and Public Vaccinator for No. 1 District of the Pembroke Union, vice Reid, resigned.

Smith, F. A. A., M.D., L.R.C.P.Ed., L.M., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the No. 2 District, and Medical Officer to the Workhouse of the Mere Union, Wilts, vice Provis, deceased.

Spong, W. N., M.R.C.S.E., has been appointed Medical Officer to the Faversham Union Workhouse, vice Spyers, deceased.

Stedman, F., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Castleton District of the Chapel-en-le-Frith Union, vice Haslewood, resigned.

Thompson, J., A.B., M.B., L.K.Q.C.P.I., M.R.C.S.E., has been appointed to the Police Force for the Borough of Royal Leamington Spa.

Tomkins, H., L.S.A.L., has been appointed a Physician's Assistant to the Royal Infirmary and Dispensary, Manchester, vice Gallimore, resigned.

Wadsworth, R., L.R.C.P.Ed., L.F.P. & S. Glas., has been reappointed Assistant Medical Officer to the Shoreditch Parochial Infirmary, Kingsland-road.

Wilson, A., M.R.C.S.E., has been appointed a Physician's Assistant to the Royal Infirmary and Dispensary, Manchester, vice Smith, appointed Senior House-Surgeon.

Births, Marriages, and Deaths.

BIRTHS.

Cartwright.—On the 30th ult., at Leintwardine, Herefordshire, the wife of John A. T. Cartwright, Surgeon, of a daughter.

Ferrier.—On the 3rd inst., at Upper Berkeley-street, Portman-square, the wife of David Ferrier, M.D., of a daughter.

Inglis.—On the 31st ult., at Worcester, the wife of A. M. Inglis, M.D., of a son.

Leake.—On the 31st ult., at Blythe-road, West Kensington, the wife of Jonas R. Leake, L.R.C.P., Surgeon H.P. H.M.'s Army, late 80th Regiment, of a daughter.

Perry.—On the 25th ult., at Melksham, the wife of George J. Perry, M.R.C.S.E., of a son.

Roche.—On the 20th ult., at Springfield, Boswells, Chelmsford, Essex, the wife of F. E. Roche, B.A., M.D., Surgeon West Essex Militia, of a daughter.

Ticehurst.—On the 21st ult., at St. Leonard's-on-Sea, the wife of A. R. Ticehurst, M.R.C.S.E., of a daughter.

MARRIAGES.

Sangster—Hatfield.—On the 28th ult., at St. George's, Tufnell-park, Holloway, Alfred Sangster, M.B., to Ann, daughter of the late John Hatfield, Esq.

Williams—Pink.—On the 29th ult., at St. Alphege, Greenwich, Leonard Williams, M.B., to Bessie Frances, daughter of H. N. Pink, Esq.

DEATHS.

Bragge.—On the 9th of May, at Hawthorn, near Melbourne, Australia, John de la Roche Bragge, M.R.C.S.E., aged 58.

Byrne.—At Great Brunswick-street, Dublin, Thos. Byrne, M.B., F.R.C.S.I., aged 73.

Franklin.—On the 2nd inst., at Folkestone, H. Franklin, C.B., Inspector-General of Hospitals, aged 88.

Jones.—On the 26th ult., at Ystrad, Geo. T. Jones, L.R.C.P.Ed., late Medical Superintendent of the North Wales Counties Lunatic Asylum, Denbigh, aged 55.

La Croix.—On the 24th of June, at Roseau, Dominica, Frederic La Croix, M.R.C.S.E., late of Winchester, aged 50.

M'Keever.—On the 31st of May, at Dublin, Thomas M'Keever, M.D., aged 84.

Pridie.—On the 19th ult., at Edinburgh, Robt. Pridie, M.D., aged 68.

Thomas.—On the 19th ult., at Hardy-street, Liverpool, Richard Thomas, Surgeon, aged 39.

[N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*]

Notes, Short Comments, and Answers to Correspondents.

THE SCHOOL OF SALERNO.

MUCH doubt hangs over the origin of this famous temple of physic, and particularly over the genesis of its "Regimen Sanitatis." A few notices, therefore, culled from a recent Italian chronicler, who has investigated the facts anew, may not be unacceptable. From the ninth century onwards, physicians of note were found in Salerno, flourishing under the protection of the Norman Princes, who possessed the city, together with Apulia and Calabria. At the close of the eleventh century, Robert, one of the three sons of William the Conqueror, was returning from Palestine to England, where the crown, which had become his through the death of his elder brother, awaited him. On his way he stopped at Salerno to get cured of a fistula contracted during the siege of Jerusalem, and, thanks to the skill of the Salernitan surgeons, his cure was complete. Before taking his leave, he asked them for a "rule of life" to keep himself in good health, and accordingly they set themselves to the task of compiling a book of sanitary precepts. The chief contributor to it was the most learned of their number, John of Milan, and in the year 1100 it duly came forth. Its success was immediate. Edition followed edition—the chief commentators being Arnaldo da Villanuova, the physician of Charles II. of Anjou; the two Giacomi, Curio and Crellio; and, finally, Renato Moreau and Zaccaria Silvio. It brought much fame and many students to Salerno, which accordingly took the lead among the medical schools of the Continent for many years. Between 1480 and 1763 it was published in almost innumerable forms, with translations into all the European languages. In some respects the best is that edited at Pavia, with an Italian version by the Cavaliere Magenta. Its "wise saws" are worthy even yet of "modern instances." What can be better than this, for example?—

> "Si tibi deficiant medici, medici tibi fiant
> Hæc tria: mens læta, requies, moderata diæta."
>
> "Where doctors are not, be thy doctors then
> Contentment, ease, and moderate regimen."

The "restorative school" cannot but subscribe to the following summary of the Salernitan *menu*:—

> "Ova recentia, vina rubentia, pinguia jura
> Cum similâ purâ naturæ sunt valitura."
>
> "Fresh eggs, red wine, and juicy broth to sup
> With wholesome bread, keep nature's system up."

We cannot suppose the homœopathists will claim the Salernitan school as addicted to the "similia similibus" dogma on the strength of this couplet:

> "Si tibi serotina nocet potatio, vina
> Horâ matutinâ rebibas et erit medicina."
>
> "The wine that, taken over-night, has hurt you
> May prove, next morning, not without its virtue."

But *jam satis*. That a collection of precepts so quaint, and, for their time, so shrewd and so popularly accepted, has hitherto found no adequate editor or translator in England is as much a "curiosity of literature" as the book itself.

Enquirer, (Manchester.)—The lectures were delivered at the College of Surgeons by Dr. Brown-Séquard.

Dr. Henry Thompson's lecture shall appear in an early issue.

MILITARY TYRANNY.

To the Editor of THE LANCET.

SIR,—A relative of mine, an officer in the army, on his last return from foreign service, was strongly advised by one of the most distinguished surgeons in Brighton to wear a beard as a preventive measure against diseases of the throat, to which he is liable, and which, while of no great gravity in themselves, might, if unchecked, lead ultimately to most serious chronic complaints. Armed with a medical certificate from this gentleman, my relative was granted permission to wear his beard, and this he has continued to do for some years with great benefit. Thoroughly healthy in all other respects, he was more exposed to the trying weather at Dartmoor than probably any other officer there, and he has done duty at all the manœuvres since with equal immunity from any evil results beyond an occasional soreness of the throat. He has now received a peremptory order to shave immediately after the close of the present manœuvres, and that in spite of strong medical certificates adverse to such a course. The result will be that either this officer (a notoriously able, zealous, and appreciated public servant) will have to surrender his professional prospects, and that the public will not only lose a good officer, but will have to pay some £200 a year (his half-pay) for twenty or thirty years for losing him, or that he must risk his health by shaving, in defiance of the strongest medical advice to the contrary.

Now for the *reductio ad absurdum*. This same officer is permitted to wear a beard in any warm country, and only expected to shave on return to this inclement climate (all the more inclement to those who have to serve in such varied climates). Again, the marines, both officers and men, are not only permitted, but are expected to wear beards when serving at home and doing permanent garrison duty alongside of those who in no way particular differ from them, except in that one detail of having smooth chins.

It has always been understood in the army that upon all subjects of health medical orders were to override every other consideration. Perhaps some of your correspondents can inform me whether the medical advisers of the Horse Guards were consulted at all in this matter. I think I may at all events depend upon you to disappoint those who thus set up their opinion upon a medical question as superior to that of medical men.

I remain, Sir, yours truly,

July, 1875. EVERY MAN TO HIS OWN TRADE.

DAMIANA.

DR. J. J. CALDWELL, of Baltimore, calls attention in the *Medical Monthly* (New York) to a plant "new to the medical world," named damiana, to which he ascribes powerful aphrodisiac properties, and which is found on the western borders of Mexico. The tincture and extract of the plant are said to increase the flow of urine as well as the sexual appetite. The virtues of damiana are believed to reside both in the root and in the leaves. There are two classes of the plant. The best bears a white blossom and has a small leaf; the other has a yellow blossom and a large leaf, and is much inferior in aroma and strength to the former.

Mr. W. M. Farnell, (Cape Town.)—We cannot give space for the paragraph. It is a quack remedy. The disease is not curable.

A Visitor.—We must decline to notice the matter at present.

Mr. Lowe, (Lincoln.)—Next week.

THE TREATMENT OF CONTAGIOUS DISEASES.

To the Editor of THE LANCET.

SIR,—A great deal has been said and written of late in reference to the erection of hospitals for the isolation and treatment of contagious diseases. This discussion has, for the main part, been limited to the question of the selection of an intra- or extra-mural site for such hospitals; but, with your permission, I am desirous of raising the larger question whether the time has not arrived when the whole subject of the suppression of contagious, and therefore preventable, diseases should be considered with a view to efficient and sufficient legislative action.

We have heard a good deal about "*Sanitas sanitatum, omnia sanitas*," since it was made an election cry of; but next to nothing has been done. The Public Health Act was passed before this cry was raised, and in it measures are indicated rather for the *repression* of contagious diseases than for their *suppression*. I say indicated; for its provisions are, for the main part, permissive, and not compulsory. Permissive Acts of Parliament are, as I understand them, educational in their chief purpose; but I trust they are meant to lead up to their logical sequence, Compulsory Acts of Parliament, if people will not do what they are taught is for their own and for the common good. None, I presume, but Malthusians will deny that the utter suppression of contagious diseases must be for the greatest and highest good of the people. Bountiful nature has afforded us exceptional facilities for such suppression. Composed of islands, our country is surrounded by a sanitary cordon of a most perfect character. International intercourse will, doubtlessly, lead to the breaking of this cordon from time to time whatever may be done; but this danger may be greatly lessened, if not obviated, by the institution of a scientific quarantine.

For the successful suppression of contagious diseases in this country, it appears to me that the following provisions are imperatively required:—

1st. That contiguous to every centre of population there shall be provided a hospital for the reception and treatment of all cases of contagious disease which may occur in that population. Isolation as perfect as may be compatible with necessary accessibility being secured by the selection of the most eligible site on which to erect such hospital.

2nd. That there shall be compulsory registration of disease. Registration of the "cause of death" only enables our sanitary officers in too many cases to "lock the stable door after the horse is stolen."

3rd. That local sanitary authorities shall have power, and it shall be their duty, to compel the prompt removal of contagious cases to the hospital provided for their reception.

Were this the "law of the land," we should in a very short time, as I believe, "stamp out" contagious diseases, and on their reimportation "nip them in the bud."

I know there will be a great outcry against such stringent legislation raised by many, but mostly by the short-sighted. As you have well said on a kindred subject, resistance will be more likely to come from the "rich and selfish" than from the poor. It will be said, "I would pay any money or run any risk rather than my dear child should be taken from its home to a hospital." But surely such an objector can be made to see, if he does not care about the common weal, that the temporary removal of one member of a family from beneath the roof-tree, for more thorough and perhaps skilful treatment, may be for the good of that member, and must be for the good of all the other members of that family. At all events, if the "times are not ripe" for obtaining legislation which shall prevent the annual sacrifice of thousands on thousands of our people to the Moloch of contagious disease, there can be no doubt the time has arrived when the question of the desirability of such legislation should be well agitated with a view to forming the necessary "public opinion."

I am, Sir, your obedient servant,

Brighton, August 2nd, 1875. JOSEPH STEPHENS, M.D.

THE LEGAL VIEW OF INSANITY.

D. C. L.—The juries show more than common sense. They show that they recognise the truth that doctors know more of insanity than lawyers, and refuse to take the direction of the Judges.

Mr. Thomas Savill.—We heartily congratulate our young friend. The examination is very severe. We believe the percentage of "plucks" is about 65.

PRESCRIPTIONS *versus* DISPENSING.

To the Editor of THE LANCET.

SIR,—I have sometimes written to you in the interest of the profession as far as regards "a return" for their labours. I have met with a glaring instance to-day only of how the "workers" are robbed in the present day of their just rewards. A gentleman came into a chemist's where I happened to be, and asked the assistant to send him a copy of a prescription, as he wanted to send it into the country to a friend, he having previously borrowed it of another friend, and having returned it without copying it. This was consented to. I remarked afterwards to the assistant that such a proceeding appeared to me to be a system of wholesale defrauding of prescribers. He told me it was a constant practice, and that it was very difficult for them to refuse. Another chemist only the other day told me he always charged 5*s*. for a copy of a prescription. Well may junior physicians and prescribers be starving after having invested their capital and worked with their brains if this kind of thing is allowed to go on. Yours very truly,

July 23rd, 1875. M.D.

A NEW INVENTION.

A NEW variety of cooking stove has recently been brought to London from New York, which for summer work commends itself to favourable attention. The apparatus consists essentially of an oven, placed by means of a sort of tripod over a large lamp, with several felt wicks burning kerosene oil. The essential peculiarity of this lamp is that the wicks are constantly surrounded with water, which keeps them cool, and prevents any charring at the burning point, so that no smoke or smell is produced. The ovens may be obtained of several sizes. Meats can be roasted or boiled, bread pies, &c. baked, and water heated. The entire first cost is about £3, and the oil consumed costs about one halfpenny an hour.

Mr. H. G. Dyer, (Ringwood.)—We quite concur in the opinion formed by our correspondent of the pamphlet. It might be well to forward a copy to the Secretary of the Society for the Suppression of Vice.

Lord Osborne is thanked for his communication.

THE DEATH UNDER CHLOROFORM AT QUARRY BANK.

To the Editor of THE LANCET.

SIR,—I enclose my notes of the case of Matilda Wyatt, of Quarry Bank, to which you allude in your impression of the 31st ult. I had fully intended sending them before, but was prevented by great pressure of professional work.

I most sincerely trust that, in the interests of fair play, which you always uphold, you will publish the details of this case. I send at the same time a slip from a local paper, which will afford you full details of the evidence given at the inquest.

I think I have cause to complain of the way in which the evidence of Mr. Ashmead was given, and I beg to draw your particular attention to the points on which he laid most stress.

1. That the cause of death was suffocation. "The face," he said, "was swollen and discoloured, and bloody froth was exuding from the mouth and nostrils."

2. That she was an unfit subject for chloroform. This he most certainly did say in the first instance, though he withdrew it on cross-examination.

3. That the lungs were consolidated and extensively diseased. This he also very much modified afterwards, saying there was *only part* of the lungs consolidated.

4. That the nature of the abdominal attack was peritonitis, and that an operation was useless.

One other point I would draw your attention to was this: that the coroner allowed him to name his own time for the post-mortem, giving directions to the police to let us (Mr. Pearse and myself) know the time, in order that we might be present. I received a telegram from Brierley Hill at 5 P.M., stating that the post-mortem would take place at 6 P.M. I accordingly, at great inconvenience, went to the house at 5.55 P.M., where I met Mr. Pearse. We both remained until 6.55 P.M., but Mr. Ashmead did not make his appearance. We were then obliged to leave, both having engagements; but in returning home I met Mr. Ashmead on his way to the house. This was at 7.25 P.M., and he offered no apology whatever for the delay in keeping his own appointment.

With these few remarks I will leave the case in your hands, feeling confident you will act with your usual justice and impartiality.

I am, Sir, yours truly,
Cradley Heath, Staffordshire, Aug. 3rd, 1875. HUGH R. KER.

P.S.—I am unable to conceive how, in a case of death "from suffocation and impeded circulation through the lungs," the cavities of the heart could be entirely empty; and how in ordinary peritonitis so large a quantity of pus would be contained in the cavity of the abdomen.

On May 26th last I was called to see Matilda Wyatt, of Quarry Bank. I found her suffering from double pleuro-pneumonia of considerable severity. The patient continued for about ten days in a very critical state, about which time the respirations and pulse began to become less frequent. She continued to improve, though the temperature was never greatly reduced, until the fourteenth day, when the temperature again considerably increased, and she complained of great tenderness over the left ovary. I found the menses had ceased at the commencement of her illness, and had not reappeared. Most uncontrollable sickness came on about this time, and the pain was at times intolerable, accompanied by rigors. The temperature reached on several occasions 105°. I have unfortunately, however, lost the notes I took at the time of the temperature, and am therefore obliged to speak from memory on this point. About fourteen days after this, or four weeks from the commencement of the attack, I first noticed a distinct hardness over the left ovary, which gradually increased in size and in distinctness of limits. A week after this, or five weeks after the attack, I examined the girl very carefully, externally and per vaginam. I found fair breathing over nearly the whole of the left lung, and also over the upper lobe of the right lung. There was, however, considerable dulness over both bases and the middle and lower lobe of right lung. On examining the abdomen, I found the left iliac fossa apparently occupied entirely by a large hard tumour, extending upwards almost on a level with the umbilicus. On percussion, I found dulness over the whole of the swelling; but the right side was distinctly resonant, giving me the impression that the intestines were pushed over entirely to that side. On examination per vaginam, I found the uterus pushed to the right side, and occupying a considerably lower position than normally. There was a distinct bulging of the left wall of the vagina, though no fluctuation could be discovered either here or externally. I found the examination, even when using the greatest care, caused the patient most exquisite pain. I then explained to the mother the nature of the case as well as it was possible, and told her that, as soon as the patient was able to bear it, I should have to give her chloroform, and pass in a needle to draw off the matter. At the end of another week I found distinct fluctuation, and, in conjunction with Mr. Pearse, I determined to draw off the matter by means of the aspirator. The opinion I had formed of the case was that there was a large abscess occupying a great part of the left side of the pelvis; that the inflammatory mischief had probably commenced about the broad ligament, and was traceable in its origin to the sudden cessation of the menstrual flux.

July 7th.—Chloroform being administered by Mr. Pearse, a further examination was instituted, which resulted in confirming us in our diagnosis. Up to this period nothing untoward had occurred beyond a little struggling at the commencement of giving chloroform. I then took the aspirator needle in my hand, and was just going to plunge it in, when violent sickness came on. We desisted until the sickness had ceased, and then, finding that she had become partially conscious, Mr. Pearse proceeded to put some more chloroform into the inhaler. Just at this moment a gurgling noise was heard distinctly by Mr. Pearse and myself, and we were under the impression at the time that the bowels had been moved. Mr. Pearse then determined to give her some more chloroform; but just as he was going to place the inhaler over the mouth she gave one gasp and died. We immediately resorted to artificial respiration, and gave brandy, but to no purpose.

On talking the matter over afterwards, I suggested to Mr. Pearse that the abscess had probably ruptured into the peritoneal cavity, and caused death by syncope, and that the gurgling noise which we had heard must have been the rupture and diffusion of the pus. We found that no fæces had been passed.

Autopsy.—By order of the coroner the body was opened on Saturday, July 10th, by Mr. Geo. Ashmead. On opening the chest, extensive pleuritic adhesions were found on the right and left side, principally towards the bases and over the middle lobes. There was a small abscess in the middle lobe of right lung, containing about half an ounce of pus. The middle and lower lobe of right lung and lower lobe of left lung were *partially* consolidated; air distinctly escaped in numerous bubbles on pressure, but no part of the lung was placed in water. The heart was entirely empty, and perfectly healthy. On opening the abdomen, a large abscess was discovered, occupying apparently the whole of the left iliac fossa, and extending upwards as far as the umbilicus. In this part the wall of the abscess appeared to have become continuous with the wall of the abdomen. The whole of the intestines were entirely pushed over to the right side of the abdomen, to the right of the median line. About one and a half to two inches below the umbilicus the sac had ruptured, and a considerable quantity of the pus had escaped into the peritoneal cavity.

Mr. Ashmead did not, in my presence, make any further examination as to the origin of the abscess or the amount of pus in the cavity. I should certainly think from appearances that there must have been at least three pints of pus in the cavity of the abscess.

The fact of the right side of the heart being empty precludes the idea of death from suffocation. The very plain evidence of a large sac containing pus having burst in the abdomen points to syncope as the cause of death, curiously coincident with the administration of chloroform.

"VERMOUTH."

A CORRESPONDENT asks for information as to the properties and physiological action of vermouth, and whether it is, as represented, "a perfect tonic."

Mr. Berry's cases shall appear in an early number.

Enquirer, (Walsall.)—Dr. Eustace Smith on Wasting Diseases of Childhood, Churchill's Diseases of Children, and Dr. Walshe on Diseases of the Heart.

THE NARCOTIC INFLUENCE OF RAILWAY TRAVELLING.

To the Editor of THE LANCET.

SIR,—In your interesting paragraph on the above (24th July) we have an accidental definition of sleep, "a loosening of the links which bind together the centres of sensation and consciousness." If we take this statement to be true as it stands, it follows that there can be sensation without consciousness and consciousness without sensation, and that it is the conjunction of sensation and consciousness which is the waking state. To my thinking the whole of these statements are wrong, and if they are, there cannot be such a thing as the phenomenon of narcotism by the vibrations of sound gently loosening those links, &c. Consciousness is very far from being proved to be absent from any being or thing, and certainly seems to be the necessary conjunct of sensation and motion. To these two—sensation and motion—belong an equilibrium necessitating a common centre. Whatever position, then, we hold consciousness to be in with regard to sensation, its position is the same with regard to motion. But we cannot imagine sensation to be existent as sensation without consciousness—i.e., without the consciousness of sensation, and ditto with motion. Now, the waking state cannot be sensation and consciousness in any conjunction, because in the waking state sensation and motion are equilibrating. But if we elaborate consciousness, or follow up its development, as it were, we shall note as the mark of the truly waking state consciousness of the *equilibrium* of sensation and motion. Whenever this consciousness fails, sleep takes place; the consciousness of sensation remains since sensation remains, and the consciousness of motion remains since motion remains, but the consciousness of their equilibrium is gone.

You say again that the narcotism is due to the vibrations of sound. This is partly true, but it is as much or more due to the so-called vibrations of light—i.e., due to the *fatigue* of the ear and eye. Of course fatigue of the ear alone, or of the eye alone, is sufficient to produce sleep, but in the case of railway travelling these are conjoined, the monotony of the sound being the cause of fatigue of the ear, and the rapidity with which objects travel into and out of sight the cause of fatigue of the eye. It is this fatigue which abolishes the consciousness of the reciprocity of sensation and motion, and fatigue is only a name to express the reaching of the natural limit of sensation and motion—i.e., the reaching of those natural bounds of being where sensation ceases to co-respond to motion, and motion to sensation, the turning-point, as it were, the pause, before they begin again to equilibrate.

I remain, Sir, yours truly,
Glasgow, August, 1875. J. S. NAIRNE.

Mr. A. Hamilton, (Edinburgh.)—The Report of Dr. Adams, headed "Cremation and Burial," will be found in the Sixth Report of the State Board of Health of Massachusetts for January, 1875, published by Wright and Potter, of Boston, U.S.

A Student.—Write to Mr. Trimmer, College of Surgeons.

Mr. Lloyd Owen, (Birmingham.)—The article shall be inserted.

MEDICAL OFFICERS OF THE INDIAN AND COLONIAL SERVICES AND REGISTRATION.

To the Editor of THE LANCET.

SIR,—I have been waiting to see whether any of your correspondents would notice my statement that all medical officers of the Indian army and colonial services are not obliged to register. I do not find the names of several of these officers whom I know in the Medical Register, although the Medical Act appears most certainly to apply to them.

Your obedient servant,
July 24th, 1875. REGISTER.

The Use of the Mosquito.

Dr. S. W. Francis (U.S.A.) thinks he has discovered the *cui bono* in the economy of nature of this pest of warm climates. He believes the mosquito was created for the purpose of driving man from malarial districts; for, in his opinion, "no region where the chills and fever prevail can be free from this little animal. Now if man will not go after the warning is given in humming accents, then the mosquito injects hypodermically a little liquid which answers two purposes—first, to render the blood thin enough to be drawn up through its tube; and, secondly, in order to inject that which possesses the principles of quinine."

Mr. John Bligh, (King's Lynn.)—Blatchley, of 362, Oxford-street.

Embolic Gangrene.

To the Editor of The Lancet.

Sir,—The following case may possibly prove of interest to some of your readers.

Miss L——, aged seventy-three, was seized on May 27th, 1875, with a sharp attack of bronchitis, attended with the ordinary symptoms and physical signs. Up to this date she had enjoyed tolerable health, never having had any serious illness, though occasionally she had suffered from rheumatic pains. There was distinct evidence, however, of valvular disease of the heart. For a week she suffered considerably from cough and dyspnœa, her sleeplessness being very distressing. Her pulse, too, was unsteady, varying a good deal both in volume and rhythm, and being at times feeble and intermittent, so that her condition seemed rather a perilous one. On June 4th, however, she began to improve, and on the 7th convalescence had so far set in that she was able to sit up in bed and read the newspaper. On the morning of the 8th she expressed herself better in every way, but complained of having had an unusual feeling of drowsiness, which lasted for a few hours the previous evening. On the night of the 8th I received an urgent message to see her at once, as "she had just had a paralytic stroke." I found her complaining of intense pain in the right arm, running down from the elbow to the fingers, and accompanied with a sensation of "pins and needles." The hand and arm, she said, felt "cold, numb, and powerless." I found she could with difficulty raise it to a level with the shoulder, but no higher. There was a good deal of venous congestion about the fingers, and they felt perceptibly colder than those of the opposite side. There had been no loss of consciousness, no pain in the head, nor giddiness. There was no existing paralysis of the right leg, right side of face, or tongue, nor any change of sensation in these parts. The right radial artery could not be felt beating, nor yet the brachial, but the axillary pulsated forcibly. Judging from the signs and symptoms that embolism of the brachial artery had taken place, due probably to the escape of some valvular deposit into the course of the circulation, I had the hand and arm wrapped in a layer of cotton-wool, ordering an opiate to relieve the pain, and a free supply of nourishment and stimulants. For the next three days there was great tenderness over the course of the brachial, and the pain in the arm continued severe, causing the patient to be very restless. By this time she had regained the power of moving the arm freely; but the fingers showed distinct signs of gangrene, which subsequently extended upwards until, at the end of the fourth week, a well-marked line of demarcation had formed at the junction of the upper and middle thirds of the forearm. Her appetite during this time was satisfactory, and her general health continued good; the treatment consisting chiefly of ammonia and bark, with an opium and chloral draught at bedtime, and plenty of beef-tea, brandy, arrowroot, &c. On July 14th dyspnœa came on, attended with sickness and failure of appetite, and on the following day she died, apparently from asthenia. No post-mortem examination was obtained.

Although embolism in a case like this may be a pure accident, which might happen to the patient under any circumstances, I am inclined to think that the extra work thrown on the heart during the previous acute attack of bronchitis would strongly predispose to its occurrence. The unusual feeling of drowsiness complained of previous to the arrest of circulation in the arm may have been significant of a similar state of things in the brain—viz., embolism of some of the cerebral vessels. In regard to diagnosis, hemiplegia in a patient of the age of seventy-three would, of course, be a probable event; but I do not think a hemiplegic limb is ever pulseless at the time of the seizure, though its circulation frequently becomes weaker than that of its fellow of the opposite side.

The case seems interesting to me—first, as occurring in a patient of this age as a sequel of acute bronchitis; and secondly, because of the sudden arrest of circulation in the limb, with rapid supervention of gangrene, and yet absence of constitutional symptoms, and postponement of death till the beginning of the sixth week.

Perhaps some of your readers can tell me if amputation has ever been done successfully in such a case. I am, Sir, yours truly,

Deal, July 26th, 1875. R. F. Quinton.

V.—The name of a pupil cannot be entered in the Students' Register before he is entered at a recognised medical school or hospital, unless he produces a certificate from the Secretary of the Royal College of Surgeons of England to the effect that his pupilage is recognised by that College as the commencement of his professional studies.

Mr. J. D. Griffith, (Chesham.)—We do not publish a list of vacant appointments. Our correspondent will find all the announcements in our advertising columns.

Sir Duncan Gibb.—Other arrangements shall be made.

Mr. Charles M. Clarke.—We think the letter rather too strong for insertion.

A County Court Verdict.

To the Editor of The Lancet.

Sir,—I was called to attend Mrs. N—— in her confinement at seven o'clock in the morning. I remained two hours. During that time she made very little progress. As it was a case of natural labour, and all was right, I thought I might safely leave her for half an hour, as I lived within three minutes' walk from the house. When I returned the child was born. I tied the cord, removed the placenta, stopped two hours, as she threatened to have hæmorrhage, and attended nine days. At the end of that period she paid half the fee, promising the rest in a few days. I summoned for the remainder. The Judge nonsuited me because I was not there when the child was born. Yours &c.,

London, July, 1875. A. W.

An Electric Fish.

Among the specimens lately added by the Zoological Society to their living collection in the Regent's-park is a small fresh-water fish belonging to the family of siluroids, and remarkable for possessing an electric organ, like the better-known *Gymnotus*, or electric eel. When touched by the fingers on the lower side of the body, it gives forth a slight, but very perceptible, electric shock. The fish is from one of the rivers of West Africa, and is known to naturalists as the *Malapterurus beninensis*, from its having been originally discovered in the River Beni. A closely allied species—the *Malapterurus electricus*—inhabits the Nile, and has been long known for its electrifying properties. It is believed that no example of any of these singular fishes has been previously brought alive to this country.

Mr. A. H. Churchill.—The County Court would be the proper Court for trying such a question, if it is worth taking into a Court, which we scarcely think the case. It is not the less shabby on the part of the patient to refuse to pay the fee.

Dr. Henry Blanc, (Poona, Bombay Presidency.)—The communication shall appear soon.

Mr. Broadhurst, (Liscard.)—Thanks.

Idiopathic Erysipelas.

To the Editor of The Lancet.

Sir,—A few weeks ago I stumbled across a couple of rather queer cases of idiopathic erysipelas. I have never seen anything to resemble them. I cannot find any reference to such cases in books; and as two or three medical practitioners of some experience have never met with such, I hope you will allow me to submit them to the kind notice of the readers of your valuable journal, because there is always a chance for a young observer to find a mare's nest. Their character was so decided, their symptoms so coincident in period and relapse, that I have felt justified in thinking them examples of a relapsing erysipelas.

Case 1.—I was called on June 6th to see Harriet B——, aged ten. I found that she had had rigors; temperature 103°; had vomited; tongue thickly furred; refusing food; constipated; pulse 140, of moderate volume; face much swelled; eyes closed; large blebs forming on face; delirium at night. The next day the face was more swelled; contents of vesicles bloody; temperature 104°; pulse 140, not quite so good in volume; much delirium at night. On the 9th the face was less swelled; vesicles not so tense; catarrh of stomach and mouth decreasing; temperature 102°; pulse 140, firmer. On the 12th the swelling had almost disappeared; eyes open; conjunctivæ jaundiced; black scabs on cheeks; temperature 100°; pulse 100. 13th: Appetite returning; temperature 98°; pulse 94. Convalescence, seven days.—21st: Found her with relapse of all the symptoms, which continued to hang about for some days, at the end of which I had her removed to a new locality, and she made a quick recovery. I therefore concluded that this was a case of septicæmia, dependent upon her residence in a house the drainage of which I found upon inquiry to be bad. No other cases in this district.

Case 2.—On June 8th I was called to Ellen H——, aged three years. I found erysipelas commencing upon the face; temperature 102°. On the 10th the disease had spread to arms, chest, and abdomen, and on the 12th over the whole body. On the 13th it began to subside from the head and face.—16th: Slight thickening of skin only remains in places; the temperature is almost normal, the child taking food well; conjunctivæ jaundiced. Convalescence, seven days.—19th: Abscesses had formed very rapidly over the acromion and external condyle of humerus and the base of the neck on the left side.—20th: I made an incision into the one over the condyle. The abscesses that remained were rapidly drying up. On the 24th the child had a relapse; the disease again extended to the extremities, and, notwithstanding that stimulants and plenty of milk were afforded, she sank on July 12th, exhausted. No more cases in this district.

Yours truly,

Cleland Lammiman, L.R.C.P.L.,

July, 1875. House-Surgeon to Tunbridge Wells Hospital.

Non finis determinat probitatem actûs.—The matter is being fully investigated by a Commission at the present time. Therefore we think it best not to insert our correspondent's letter.

Mr. H. G. Trestrail's letter shall receive consideration.

Tyro.—At the Army Medical Department, Whitehall-yard.

The New Fever Department of the Sussex County Hospital.

To the Editor of The Lancet.

Sir,—I read last evening with much surprise a letter in your journal from Dr. Taaffe, of Brighton, making very free use of my name, and accusing me of "indirectly (a very indefinite expression) misrepresenting" him, and particularly of asserting that an article which appeared in The Lancet some weeks since upon the above subject was "inspired" by him, Dr. Taaffe. I beg to state most distinctly that I never for a moment thought or said anything of the kind. It never occurred to me that Dr. Taaffe had sufficient influence with the Editor of The Lancet to procure the writing of any such article. In fact, I never mentioned Dr. Taaffe's name either in my letter to you (which appears to have given him such great offence) or in any that I have sent to the Brighton papers.

As to the remainder of Dr. Taaffe's remarks, as the Brighton Town Council have decided by a very large majority that the proposed alterations at the Sussex County Hospital are unobjectionable, it does not appear to me necessary or desirable to prolong the discussion.

I am, Sir, your obedient servant,

William Kebbell, M.D.,

Brighton, July 31st, 1875. Physician to the Sussex County Hospital.

C. M.—Our correspondent's question has been overlooked. The firm can recover for medical attendance and medicines by virtue of the qualification mentioned.

Dr. C. Faber.—The paper may be forwarded to our Office. We shall be most happy to receive it.

Mr. Boridan.—Search shall be made for the article.

"The Odd Shilling."

To the Editor of The Lancet.

Sir,—Hitherto the correspondence respecting "the odd shilling" has been solely on one side of the question. I think there is something to be said on the other. Were this world a Utopia, the five per cent. state of affairs could not exist; but, as matters are, I contend that the debateable shilling smooths the practitioner's path immensely. Nurses have many opportunities for saving us a world of trouble. They might often send for the accoucheur long ere his aid is really required, and rouse him from his slumbers about two A.M., when they could, with a little forethought and care for the doctor's rest, permit him to remain undisturbed until a few hours have elapsed. As a young practitioner, I have generally found this the case; and were the nurses to give me unnecessary trouble, they know full well they would not receive their shillings. Of course, were nurses immaculate, their little fees would not affect their conduct; but for my own part I never regret this custom, as I am confident it secures the full alliance of those who reign paramount in the lying-in room, and this latter fact the oldest accoucheur cannot gainsay.

As regards vaccination, I always make a charge of half-a-crown for one guinea, five shillings for two and three guinea, and half a guinea for five guinea cases—a scale of charges that I find works well.

I am, Sir, your obedient servant,
London, July 24th, 1875. A. H. W. A.

Another Fraud.

To the Editor of The Lancet.

Sir,—I clipped the following advertisement from one of to-day's papers:—

"Examination.—Wanted, a gentleman to pass a simple examination in general education; will be well paid.—Medicus, Post-office."

The rogue or fool in this instance seems to have avoided the circumlocution that Mr. Gould's fool or rogue thought it primarily necessary to affect. If offers of this open nature can find ready insertion in the public prints, I fail to see why gentlemen in need of burglars, forgers, cut-throats, and so forth, should not address their peculiar public through similar channels.

Yours obediently,
July 26th, 1875. Gray's Inn.

Errata.—In Mr. Alderson's letter on Puerperal Fever, published in our last, p. 183, ninth line from the bottom of first column, for "low typhoid," read "pneumonia of typhoid type." And in the eighth line of last paragraph of the letter, for "Mr.," read "Dr."—In the obituary of Dr. Officer, p. 185, for "Dr. James," read "Dr. James Laing."—The fifteenth name in the list, published last week, of gentlemen who passed the examination for the Membership of the College of Surgeons, should have been printed "Colborne," not "Colborn."

Communications not noticed in the current number will receive attention in our issue of the ensuing week.

Communications, Letters, &c., have been received from—Mr. H. Smith, London; Dr. Henry Bennet, London; Mr. George Pollock, London; Mr. C.
